Chapter 1

Overview

Introduction

Welcome to the MX-NOS user manual. This comprehensive guide is designed to help you understand and navigate the UI features, technical concepts, and tasks you may encounter while using your device. Our goal is to simplify your experience and make the setup process easier.

About MX-NOS

Moxa's next-generation Ethernet switches are powered by MX-NOS, a tailored firmware platform that seamlessly integrates with your Moxa devices. This unlocks their full potential, transforming your switches into powerful tools with consistent functionality and a user-friendly interface.

How does Moxa achieve this? By providing a platform-based management OS, Moxa offers several key advantages, including:

- **Streamlined software management with regular updates:** Moxa keeps your switches up-to-date with the latest technologies throughout their lifetime. Continuous bug fixes and vulnerability synchronization ensure high software quality and improved network security.
- **Robust security by design:** Moxa adheres to IEC 62443-4-1 for software development lifecycles. As a result, MX-NOS provides a solid foundation for the switches running on it to build security features based on IEC 62443-4-2.
- **Consistent user experience:** MX-NOS features an intuitive UI that provides a consistent user experience across different browsing devices, minimizing training time and maximizing efficiency.

MX-NOS is more than just a firmware platform; it's a significant leap towards a superior user experience.

What's in This Document

This document includes the following sections:

- **Overview:** This section introduces this document and how to use it.
- **Quick Start:** This section tells you how to connect to your device so you can start using and configuring it.
- **UI Reference:** This section goes through the web user interface (UI) of your device to help you quickly understand what settings are available. This section also shows you the valid ranges and defaults for settings, and any limitations there may be when configuring your device.
- **Appendix:** This section provides additional reference information for your device.

Supported Series and Firmware Versions

Moxa Switch Series	Firmware Version
MDS-G4000-L2 Series	v5.1
MDS-G4000-L2-4XGS Series	v5.1
MDS-G4000-L3 Series	v5.1
MDS-G4000-L3-4XGS Series	v5.1
RKS-G4000-L2 Series	v5.0
RKS-G4000-L3 Series	v5.1

 **Note**

We are continually improving and developing our software. Check regularly to see if there is an updated version of the software that provides you with additional benefits. You can find information and software downloads on the Moxa product pages at <https://www.moxa.com/en/support/product-support/software-and-documentation>.

Product Series Feature Comparison Table

Refer to the table below for a full overview of the supported features for each product series model covered by this manual.

- **YES:** Supported
- **PARTIAL:** Partially supported
- **-:** Unsupported

For more details on partially supported features, refer to their respective sections in this manual.

How to set up

Chapter 2

Quick Start

Using a Web Browser to Configure the Industrial Ethernet Switch

The device's web interface provides a convenient way to modify the switch's configuration and access the built-in monitoring and network administration functions.

Note

When using the device's web interface, we recommend using the following browsers and versions. Please note that Internet Explorer (IE) is not supported.

- Chrome: 2 most recent versions
- Firefox: Latest version and the Extended Support Release (ESR)
- Edge: 2 most recent major versions
- Safari: 2 most recent major versions
- iOS: 2 most recent major versions
- Android: 2 most recent major versions

Perform the following steps to access the device's web interface:

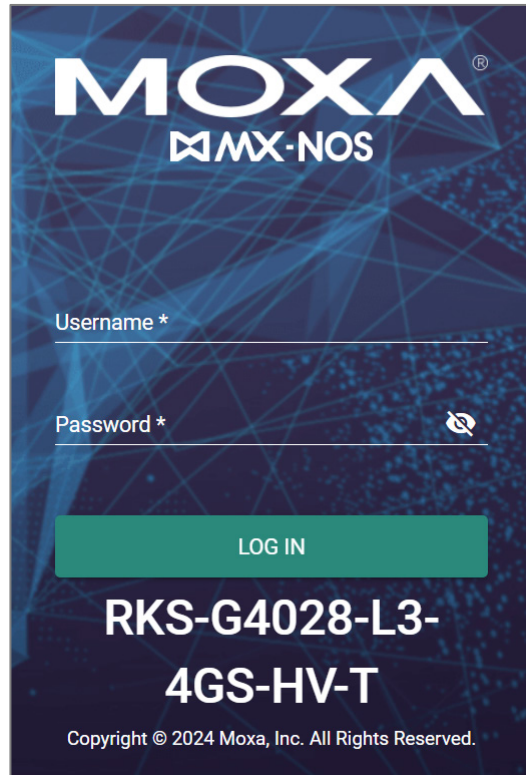

1. Make sure your PC host is connected to your device's LAN port, and is on the same subnet as your device.
2. Open a web browser and type the device's LAN IP address (**192.168.127.253** by default) into the address bar and press Enter.

3. The web login page will open. Enter the username (**admin** or **user**) and password (the same as the Console password) and click **LOG IN** to continue.

Note

The default username is admin and the default password is moxa. We strongly recommend changing the password as soon as possible to ensure the security of your device.

You may need to wait a few moments for the web interface to appear.

4. After successfully connecting to the switch, the **Device Summary** screen will automatically appear. Use the menu tree on the left side of the window to open the function pages to access each of the switch's functions.

Using a RS-232 Console to Configure the Device

You can connect to your device's serial console port to configure settings.

Perform the following steps to connect to the serial console port:

1. Prepare an RS-232 serial cable with an RJ45 interface.
2. Connect the RJ45 interface end to the console port on the device, and the other end to your computer.
3. We recommend you use PComm Terminal Emulator for serial communication. The software can be downloaded free of charge from Moxa's website.

Perform the following steps to configure your connection to access the device's console (PComm Terminal Emulator is used for these steps):

1. From the Windows desktop, click **Start > Moxa > PComm Terminal Emulator**.

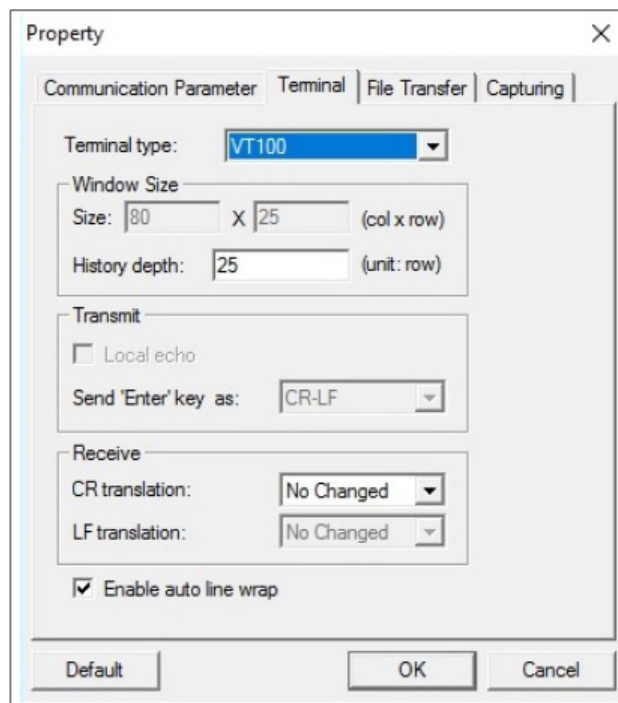

2. Select **Open** under the **Port Manager** menu to open a new connection.

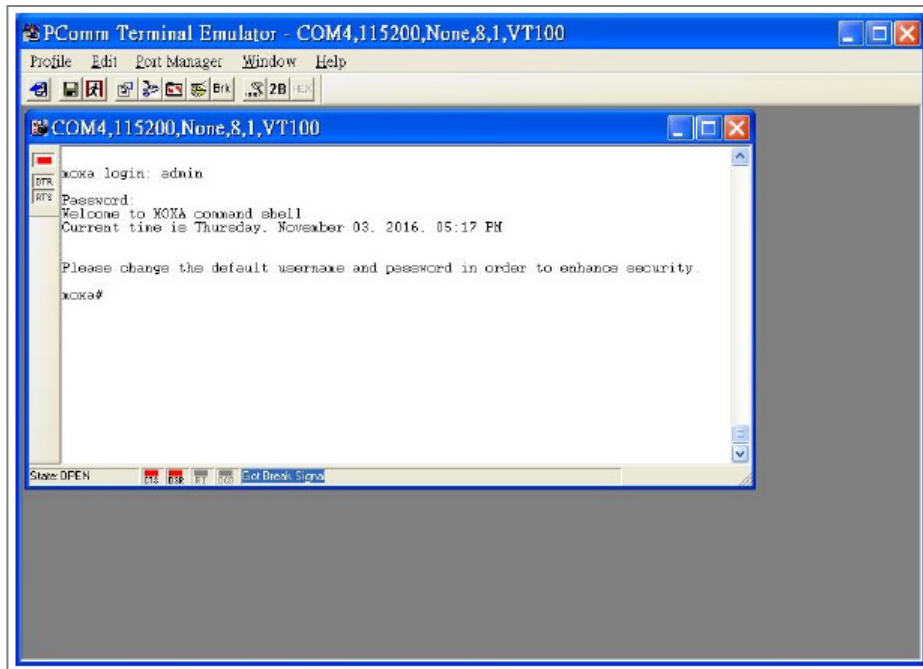

3. The **Property** window should open. In the **Communication Parameter** tab for **Ports**, select the COM port that is being used for the console connection. Set the other fields as follows: **115200** for **Baud Rate**, **8** for **Data Bits**, **None** for **Parity**, and **1** for **Stop Bits**.

4. In the **Terminal** tab, select **VT100** for **Terminal Type**, and then click **OK** to continue.

- The console will prompt you to log in. The default login name is **admin**, and the default password is **moxa**. This password will be required to access any of the consoles (web, serial, Telnet).

- After successfully connecting to the device's serial console, you can start configuring the its parameters by using command line instructions. Refer to the Moxa Command Line Interface Manual for details.

Note

By default, the password is moxa.

Make sure you change the default password after you first log in to help keep your system secure.

Using Telnet to Configure the Device

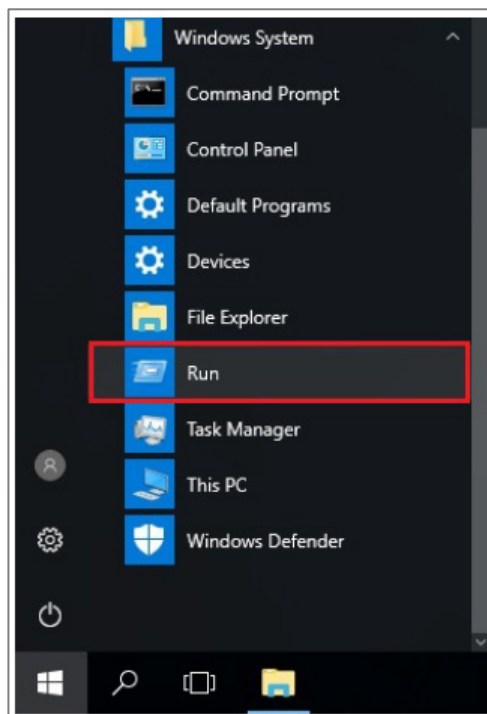

You can use Telnet to connect to the device and configure it. This requires the host and the target device to configure to be on the same logical subnet, so you may need to adjust your PC host's IP address and subnet mask. By default, the device IP address is **192.168.127.253** and the default subnet mask is **255.255.255.0**. For example, your PC's IP address must be set to 192.168.xxx.xxx if the subnet mask is 255.255.0.0, or to 192.168.127.xxx if the subnet mask is 255.255.255.0.

Note

When connecting to the device using Telnet or its web interface, first connect one of the device's Ethernet ports to your Ethernet LAN, or directly to your PC's Ethernet port. You can use either a straight-through or cross-over Ethernet cable.

After making sure that the device is connected to the same LAN and logical subnet as your PC, perform these steps to connect to your device:

1. Click **Start > Run** from the Windows Start menu, then enter telnet followed by the device's IP address. You can also issue the Telnet command from a DOS prompt.

2. The Telnet console will prompt you to log in. The default login name is **admin**, and the default password is **moxa**. This password will be required to access any of the consoles (web, serial, Telnet).

3. After successfully logging in, you can start configuring the switch parameters by using command line instructions. Refer to the **Moxa Command Line Interface Manual**.

Note

By default, the password assigned to the Moxa switch is moxa.

Make sure you change the default password after you first log in to help keep your system secure.

Chapter 3

UI Reference

UI Reference Overview

This section provides you with a quick reference to the different settings and options of your device.

To help you understand how to use the user interface, the following sections are included:

- The MX-NOS User Interface
- Options Menu

The rest of this section follows the order of the menu areas in the user interface:

The MX-NOS User Interface

Moxa's managed switches offer a user-friendly web interface for easy configuration, reducing system maintenance and configuration effort.

This section describes how the web interface is laid out to make it easier for you to find and access the different function pages.

Here is an overview of the MX-NOS user interface:

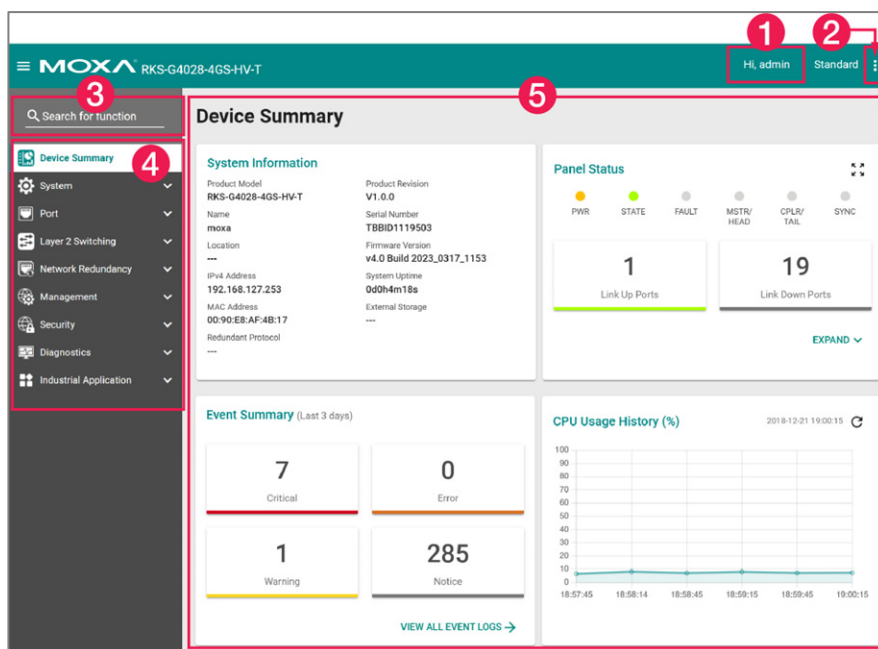

Figure 1 MX-NOS v4.0

1. **Login Name:** Shows the name of the currently logged in user.
2. **Configuration Mode:** Shows which configuration mode is being used:
 - **Standard Mode:** Some features and parameters will be hidden to make configuration simpler (enabled by default).
 - **Advanced Mode:** More features and parameters will be shown to allow for more detailed configuration.
3. **Search Bar:** Type in a function name to filter to the function menu.
4. **Function Menu:** All functions of the switch are shown here. Click the function you want to view or configure.

5. **Device Summary:** Shows device information and settings for the selected function.

Options Menu

Clicking the **Options** (⋮) icon in the upper-right corner of the page will open the options menu.

Options Menu - User Privileges

Privileges to settings are granted to the different authority levels as follows. Refer to [System > Account Management > User Accounts](#) for more information on user accounts.

Settings	Admin	Supervisor	User
Change Language	R/W	R/W	R/W
Change Mode: Standard/Advanced Mode	R/W	R/W	R/W
Disable Auto Save	R/W	R/W	-
Locator	R/W	R/W	R
Reboot	R/W	R/W	-
Reset to Default Settings	R/W	-	-

Settings	Admin	Supervisor	User
Log Out	R/W	R/W	R/W

Change Language

To change the language of the interface, click the **Options (⋮)** icon in the upper-right corner of the page, and select **Change Language**.

Change Mode

There are two configuration modes available for users: **Standard Mode** and **Advanced Mode**.

- In **Standard Mode**, some of the features/parameters will be hidden to make it easier to perform configurations. This is the default setting.
- In **Advanced Mode**, advanced features/parameters will be available for users to adjust these settings.

To switch between modes, click the **Options (⋮)** icon in the upper-right corner of the page, and select **Change Mode**.

Disable/Enable Auto Save

Auto Save allows users to save all changes to the device's running configuration to the startup configuration immediately and automatically, so all changes will persist even after the device has restarted. Refer to [Configuration Types](#) for more information about the different configurations your device uses.

Note

Auto Save is enabled by default.

To disable Auto Save, click the **Options (⋮)** icon in the upper-right corner of the page, and select **Disable Auto Save**.

To save configuration changes to the startup configuration, click the **Save** (🔒) icon.

Note

When auto save is disabled, if changes have not been saved and the device is restarted, all changes will be lost and the device will revert to its startup configuration.

To re-enable Auto Save, click the **Options** (⋮) icon in the upper-right corner of the page, and select **Enable Auto Save**.

Locator

The Locator feature will cause the LED indicators on the device to flash, making it easier to locate and identify the specific device when installed at a field site.

To trigger the device locator, click the **Options** (⋮) icon in the upper-right corner of the page, and select **Locator**. Select how long in seconds the LEDs should flash for, then click **LOCATE**.

Reboot

To manually reboot the device, click the **Options** (⋮) icon in the upper-right corner of the page, and select **Reboot**.

Reset to Default Settings

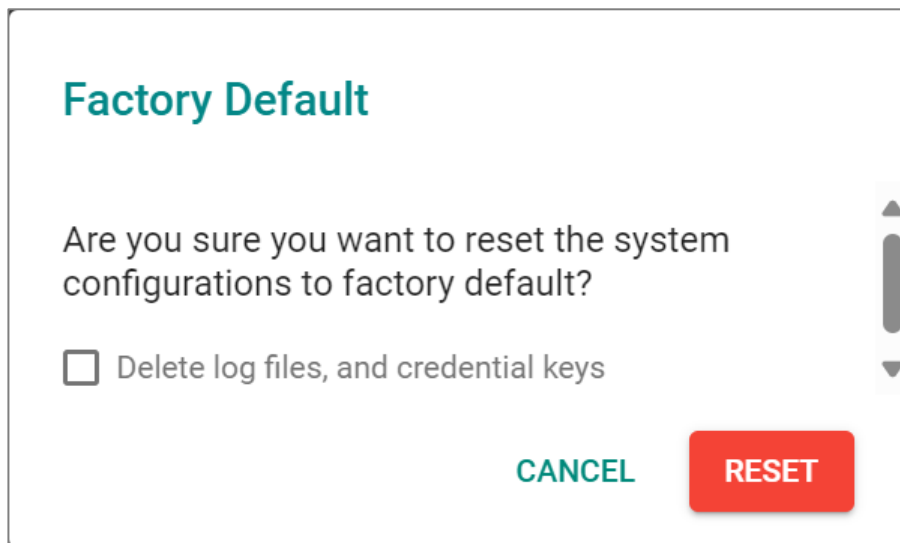

To reset the device to its default settings, click the **Options** (⋮) icon in the upper-right corner of the page, and select **Reset to Default Settings**.

If you want to delete all event logs and the certificate database, check the **Delete log files and credential keys** option. This will delete all information on the device and reset everything to its factory default value.

Click **RESET** to reset your device to the default settings.

▲ Warning

When resetting your device to the factory default settings, all your current configuration settings will be permanently deleted.

Log Out

To log out of the device, click the **Options** (⋮) icon in the upper-right corner of the page, and select **Log Out**.

Device Summary

Menu Path: Device Summary

This page lets you see the current status of your device through a variety of display panels.

System Information

This display shows basic information about your device and its current status.

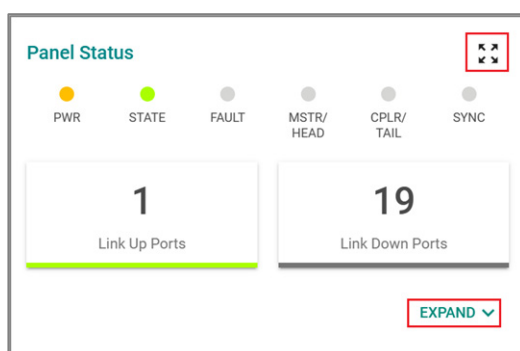

System Information	
Product Model	Product Revision
RKS-G4028-PL-PoE-12XGS-T	V0.0.0
Name	Serial Number
moxa	MOXA00000000
Location	Firmware Version
---	v5.0 Build 2025_0926_0143
IPv4 Address	System Uptime
192.168.127.253	6d23h53m30s
MAC Address	External Storage
00:90:E8:98:DF:32	---
OOB IPv4 Address	Redundant Protocol
10.123.33.44	---
OOB MAC Address	System Temperature
00:90:E8:98:DF:4F	41.50°C/ 106.70°F

UI Setting	Description
Product Model	Shows the product model of the device.
Name	Shows the name of the device. Refer to System > System Management > Information Settings for more information.
Location	Shows the location of the device. Refer to System > System Management > Information Settings for more information.
Interface IP Address List	Shows the IP address of the device's interface. Click on the arrow to go to the Network Interface page.
MAC Address	Shows the MAC address of the device.

UI Setting	Description
OOB IPv4 Address	Shows the Out of Bounds Management IPv4 address of the device.
OOB MAC Address	Shows the Out of Bounds Management MAC address of the device.
Product Revision	Shows the product revision of the device.
Serial Number	Shows the serial number of your device.
Firmware Version	Shows the firmware version of your device.
External Storage	Shows the external storage device currently connected to your device, if applicable.
System Uptime	Shows the amount of time your device has been continuously running for.
Redundant Protocol	Shows the current redundancy protocol for this switch.
System Temperature	Shows the current system temperature of your device.

Panel Status

This display reflects the current status of the physical LEDs on your device, and shows how many ports currently have a link up or link down status. Grey is used to indicate an LED is off. For more information about status LEDs and their behavior, please refer to the QIG.

Click **EXPAND** to view more detailed information, or click **COLLAPSE** to return to the compact view.

Panel View

By clicking the **Expand** (⌕) icon in **Panel Status**, you can see a visual representation of your device's ports.

Green ports have an active link. You can move your cursor over a port to show a mouseover with more information about that port.

Click the **Close** (X) icon to close the **Panel View** and show **Panel Status** again.

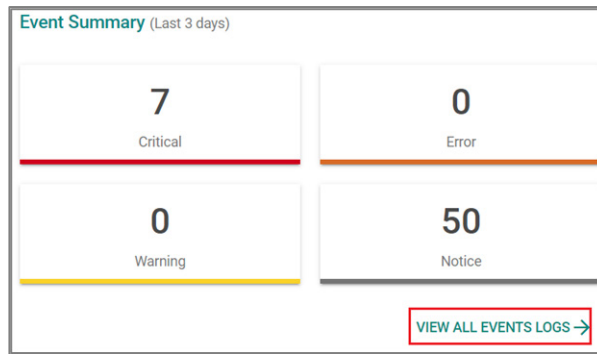

Note

The Panel View figure may vary depending on the device and the modules installed in it.

Event Summary (Last 3 days)

This display shows an event summary for the past three days. Click **VIEW ALL EVENT LOGS** to go to the Diagnostics > Event Logs and Notifications > Event Logs page to view more detailed information.

CPU Usage History (%)

This display shows the device's CPU usage shown as a percentage over time. Click the **Refresh** (🔄) icon to refresh the graph.

System

Menu Path: System

This section lets you adjust various system settings.

This section includes these pages:

- System Management
- Account Management
- Management Interface
- Time

System - User Privileges

Privileges to System settings are granted to the different authority levels as follows.

Refer to [System > Account Management > User Accounts](#) for more information on user accounts.

Firmware Upgrade

Menu Path: System > System Management > Firmware Upgrade

You can upgrade the firmware through the following methods:

- Local
- TFTP
- SFTP
- USB
- microSD

Note

It is highly recommended that you back up your device's configuration before upgrading the firmware. Refer to System > System Management > Configuration Backup and Restore for more information.

Note

If it is necessary to verify the integrity and signature of the application when the system is running, the administrator can use the show integrity check CLI command.

Warning

Upgrading the firmware should be only be done by qualified personnel, as it is possible to render the device inoperable if the upgrade is not done properly. If you are not familiar with the process, please request the assistance of qualified personnel. You can also consult with Moxa support and we will provide you with the necessary assistance.

Before performing a firmware upgrade, make sure you take the following precautions:

- Back up your configuration before upgrading the firmware
- Ensure that the device has power during the entire process
- Ensure that your computer stays connected to the device you are upgrading the firmware on
- Make sure the connection to the firmware source is not interrupted during the upgrade process

Firmware Upgrade - Local

If you select **Local** as your **Method**, these settings will appear. The Local method lets you upload firmware directly from local storage on the host device.

Note

Before performing a firmware upgrade, download the updated firmware (*.rom) file first from Moxa's website (www.moxa.com).

The screenshot shows the 'Firmware Upgrade' interface. At the top, the title 'Firmware Upgrade' is displayed. Below the title, there is a dropdown menu labeled 'Method *' with 'Local' selected. Underneath, there is a 'Select File *' field with a folder icon to its right. At the bottom left, there is a green 'UPGRADE' button.

UI Setting	Description	Valid Range	Default Value
Select File	Select the new firmware file (*.rom) to use from your computer.	Select a file from your computer	N/A

Firmware Upgrade - TFTP

If you select **TFTP** as your **Method**, these settings will appear. The TFTP method lets you upload and install firmware stored on a remote TFTP server.

The screenshot shows the 'Firmware Upgrade' interface with 'Method' set to 'TFTP'. The 'Method *' dropdown menu is highlighted in blue and shows 'TFTP' selected. Below this, there are two input fields: 'Server IP Address *' and 'File Name *'. At the bottom left, there is a green 'UPGRADE' button.

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the TFTP server where the new firmware file (*.rom) is located.	Valid IP address	N/A
File Name	Specify the filename of the new firmware.	File name	N/A

Firmware Upgrade - SFTP

If you select **SFTP** as your **Method**, these settings will appear. The SFTP method lets you upload and install firmware stored on a remote SFTP server.

Firmware Upgrade

Method *
SFTP

Server IP Address *

File Name *

Account *

Password *

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the SFTP server where the new firmware file (*.rom) is located.	Valid IP address	N/A
File Name	Specify the filename of the new firmware.	File name can only contain A-Z, a-z, 0-9 or the symbols -._().	N/A
Account	Enter the SFTP server account name to use to connect to the SFTP server.	Account	N/A
Password	Enter the SFTP server account password to use to connect to the SFTP server.	Password	N/A

Firmware Upgrade - USB

If you select **USB** as your **Method**, these settings will appear. The USB method allows you to upgrade the firmware via Moxa's USB-based ABC-02 configuration tool.

 **Note**

To use this feature, USB Function must be enabled in System > Management Interface > Hardware Interface.

The screenshot shows a web interface titled "Firmware Upgrade". It features a dropdown menu for "Method *" with "USB" selected. Below it is a "Select File *" field with a folder icon and a green "UPGRADE" button.

UI Setting	Description	Valid Range	Default Value
Select File	Select the new firmware file (*.rom) to use from your USB device.	Select a file from the USB device	N/A

Firmware Upgrade - microSD

If you select **microSD** as your **Method**, these settings will appear. The microSD method allows you to upgrade the firmware via Moxa's USB-based ABC-03 configuration tool.

Note

To use this feature, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.

Firmware Upgrade

Method *
microSD

Select File * 

UPGRADE

UI Setting	Description	Valid Range	Default Value
Select File	Select the new firmware file (*.rom) to use from your USB device.	Select a file from the microSD device	N/A

Configuration Backup and Restore

Menu Path: System > System Management > Configuration Backup and Restore

This page helps you back up and restore your device configuration.

This page includes these tabs:

- Backup
- Restore
- File Encryption
- File Signature

Configuration Backup and Restore - Backup

Menu Path: System > System Management > Configuration Backup and Restore - Backup

This section lets you create a backup of the current device configuration.

There are multiple methods of backing up the device configuration:

- Local
- TFTP
- SFTP
- USB
- microSD

Note

For security reasons, we strongly recommend that you back up the system configuration to a secure storage location periodically.

Configuration Backup - Local

If you select **Local** as your **Method**, these settings will appear. The Local method will export the configuration backup file to the local host.

Method *

Local ▼

Select Configuration *

Running Configuration ▼

Default Configuration *

Not Included ▼

BACK UP

UI Setting	Description	Valid Range	Default Value
Select Configuration	Choose to back up the running configuration or the startup configuration of the switch.	Running Configuration / Startup Configuration	Running Configuration
Default Configuration	Choose to back up the configuration without or with default settings.	Not Included / Included	Not Included

Configuration Backup - TFTP

If you select **TFTP** as your **Method**, these settings will appear. The TFTP method lets you upload the configuration backup file to a remote TFTP server.

Method *

TFTP

Server IP Address * File Name *

BACK UP

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the TFTP server to upload the backup to.	Valid IP address	N/A
File Name	Specify a filename for the backup, including its full path on the server. Example: /path_to_configuration_file/configuration_file.conf	N/A	N/A
	<p>Note</p> <p>If a path is not specified, the default folder for the server will be used.</p>		

Configuration Backup - SFTP

If you select **SFTP** as your **Method**, these settings will appear. The SFTP method lets you upload the configuration backup file to a remote SFTP server.

Method *
SFTP

Server IP Address * File Name *

Account * Password *

BACK UP

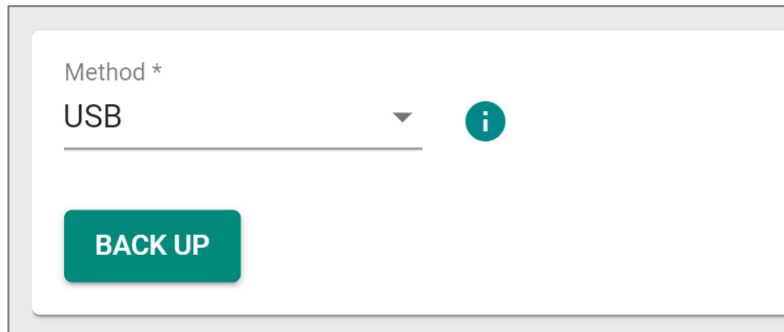

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the SFTP server to upload the backup to.	Valid IP address	N/A
File Name	Specify a filename for the backup, including its full path on the server. Example: /path_to_configuration_file/configuration_file.conf	File name can only contain A-Z, a-z, 0-9 or the symbols -.(_).	N/A
	<p> Note</p> <p>If a path is not specified, the default folder for the server will be used.</p>		
Account	Enter the SFTP server account name to use to connect to the SFTP server.	N/A	N/A
Password	Enter the SFTP server account password to use to connect to the SFTP server.	N/A	N/A

Configuration Backup - USB

If you select **USB** as your **Method**, these settings will appear. The USB method allows you to export the configuration backup file to a Moxa ABC-02 configuration tool connected to the device. Insert a Moxa ABC-02 configuration tool into the USB port of the switch, then click **BACK UP** to back up the system configuration file.

Note

To use this feature, USB Function must be enabled in System > Management Interface > Hardware Interface.

Configuration Backup - microSD

If you select **microSD** as your **Method**, these settings will appear. The microSD method allows you to export the configuration backup file to a microSD card inserted into your device.

Note

To use this feature, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.

Auto Configuration Backup

Auto configuration backup lets you automatically back up the configuration file to an ABC-02 configuration tool or microSD card whenever the configuration is changed.

To enable automatic backup, select **Enabled** from the drop-down list, then click **APPLY**.

UI Setting	Description	Valid Range	Default Value
Automatically Back Up	<p>When enabled, this will back up the current configuration to an inserted ABC-02 configuration tool or microSD card.</p> <p>Note To use an ABC-02 configuration tool, USB Function must be enabled in System > Management Interface > Hardware Interface.</p> <p>To use a microSD card, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.</p> <p>Note If both an ABC-02 configuration tool and a microSD card are inserted into the device, the ABC-02 configuration tool will be used.</p>	Enabled / Disabled	Enabled

Configuration Backup and Restore - Restore

Menu Path: System > System Management > Configuration Backup and Restore - Restore

This page lets you restore a previously backed up configuration.

There are multiple methods of restoring the device configuration:

- Local
- TFTP
- SFTP

- USB
- microSD

Note

To ensure that configuration files can be successfully imported, do not manually modify them.

Configuration Restore - Local

If you select **Local** as your **Method**, these settings will appear. The Local method will restore from a configuration file on the local host.

The screenshot shows a web interface titled "Configuration Backup and Restore". It has four tabs: "Backup", "Restore", "File Encryption", and "File Signature". The "Restore" tab is active. Underneath, there is a "Method *" dropdown menu currently showing "Local". Below that is a "Select File *" field with a folder icon to its right. At the bottom left of the form is a green button labeled "RESTORE".

UI Setting	Description	Valid Range	Default Value
Select File	Select the configuration file to use from your computer.	Select a file from your computer	N/A

Configuration Restore - TFTP

If you select **TFTP** as your **Method**, these settings will appear. The TFTP method lets you download and install a configuration stored on a remote TFTP server.

Configuration Backup and Restore

Backup	Restore	File Encryption	File Signature
--------	---------	-----------------	----------------

Method *
TFTP

Server IP Address * File Name *

RESTORE

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the TFTP server.	Valid IP address	N/A
File Name	Specify the file name of the configuration file to restore from, including its full path on the server. Example: /path_to_configuration_file/configuration_file.conf	Up to 54 characters, including file extension	N/A

Note

If a path is not specified, the default folder for the server will be used.

Configuration Restore - SFTP

If you select **SFTP** as your **Method**, these settings will appear. The SFTP method lets you download and install a configuration stored on a remote SFTP server.

Configuration Backup and Restore

Backup	Restore	File Encryption	File Signature
Method * SFTP			
Server IP Address *		File Name *	
Account *		Password *	
<input type="button" value="RESTORE"/>			

UI Setting	Description	Valid Range	Default Value
Server IP Address	Specify the IP address of the SFTP server where the configuration file is stored.	Valid IP address	N/A
File Name	Specify the file name of the configuration file to restore from, including its full path on the server. Example: /path_to_configuration_file/configuration_file.conf	File name can only contain the characters A-Z, a-z, 0-9, and special characters -._().	N/A
	<div style="background-color: #f0f0f0; padding: 5px;"> <p>Note</p> <p>If a path is not specified, the default folder for the server will be used.</p> </div>		
Account	Enter the SFTP server account name to use to connect to the SFTP server.	Account	N/A
Password	Enter the SFTP server account password to use to connect to the SFTP server.	Password	N/A

Configuration Restore - USB

If you select USB as your **Method**, these settings will appear. The USB method allows you to restore the configuration from a file via Moxa's USB-based ABC-02 configuration tool.

Note

To use this feature, USB Function must be enabled in System > Management Interface > Hardware Interface.

Configuration Backup and Restore

Backup | **Restore** | File Encryption | File Signature

Method *
USB 

Select File * 

RESTORE

UI Setting	Description	Valid Range	Default Value
Select File	Select the configuration file to use from your USB device.	Select a file from the USB device	N/A

Configuration Restore - microSD

If you select **microSD** as your **Method**, these settings will appear. The microSD method allows you to restore the configuration from a microSD card inserted into your device.

Note

To use this feature, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.

UI Setting	Description	Valid Range	Default Value
Select File	Select the configuration file to use from the microSD card.	Select a file from the microSD card	N/A

Auto Configuration Restore

Auto configuration restore lets you restore the device's configuration from an inserted ABC-02 configuration tool or microSD card whenever the device is rebooted.

To enable automatic restore, select **Enabled** from the drop-down list, then click **APPLY**.

UI Setting	Description	Valid Range	Default Value
Automatically Restore	<p>When enabled, this will restore the device's configuration from an inserted ABC-02 configuration tool or microSD card whenever the device is rebooted.</p> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p>Note</p> <p>To use an ABC-02 configuration tool, USB Function must be enabled in System > Management Interface > Hardware Interface.</p> <p>To use a microSD card, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.</p> </div> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p>Note</p> <p>If both an ABC-02 configuration tool and a microSD card are inserted into the device, the ABC-02 configuration tool will be used.</p> </div>	Enabled / Disabled	Enabled

Configuration Backup and Restore - File Encryption

Menu Path: System > System Management > Configuration Backup and Restore - File Encryption

This page lets you configure data encryption settings for exported configuration files.

Configuration Backup and Restore

Backup
Restore
File Encryption
File Signature

Configuration File Encryption *

Disabled ▼

Password 🔒

0 / 60

APPLY

UI Setting	Description	Valid Range	Default Value
Configuration File Encryption	Enable/disable encryption of configuration files.	Enabled / Disabled	Disabled
Password	Specify the password used to encrypt configuration files.	1 to 60 characters	N/A

File Signature

Menu Path: System > System Management > Configuration Backup and Restore - File Signature

This page lets you enable use of file signatures to help ensure the file integrity and authenticity of your configuration files.

Note

Before enabling file signatures, you will need to add a private/public key to the table on this page.

⚠ Limitations

You can add up to 1 key to use for file signatures.

Signed Configuration

The screenshot shows the 'Configuration Backup and Restore' interface with the 'File Signature' tab selected. A dropdown menu for 'Signed Configuration *' is set to 'Disabled' with an information icon. An 'APPLY' button is visible below the dropdown. Below this is a table with columns 'Key', 'Label', 'Algorithm', and 'Length'. The table is currently empty, with a '+', 'Max. 1', and '0 of 0' indicators.

UI Setting	Description	Valid Range	Default Value
Signed Configuration	Enables or disables the use of a digital signature to check the integrity of configuration files. Note To enable this feature, a private/public key must be installed first. Refer to Adding a Custom Key for more information.	Enabled / Disabled	Disabled

File Signature Key List

The screenshot shows a table with columns 'Key', 'Label', 'Algorithm', and 'Length'. It contains one entry: 'Private/Certificate' with label 'Test', algorithm 'RSA', and length '2048'. There are edit and delete icons for this entry. The table is titled 'Max. 1' and shows '1 - 1 of 1' items.

UI Setting	Description
Key	Shows whether the key is a public or private key.
Label	Shows the label used to help identify the key.
Algorithm	Shows the algorithm used for the key, such as RSA or ECDSA.
Length	Shows the length of the key in bits.

Adding a Custom Key

Menu Path: System > System Management > Configuration Backup and Restore - File Signature

Clicking the **Add** (🔑) icon on the **System > System Management > Configuration Backup and Restore - File Signature** page will open this dialog box. This dialog lets you add a custom key to use for file signatures.

Click **CREATE** to save your changes and add the new key.

UI Setting	Description	Valid Range	Default Value
Label	Specify a label to help describe the certificate and the key.	0 to 16 characters	N/A
Certificate	Select a certificate file to import from your computer.	Select a certificate file from your computer	N/A
Key	Select a key file to import from your computer.	Select a key file from your computer	N/A

Account Management

Menu Path: System > Account Management

This section lets you manage user accounts for your device. You can enable different accounts with different roles to facilitate convenient management and safe access.

This section includes these pages:

- User Accounts
- Online Accounts
- Password Policy

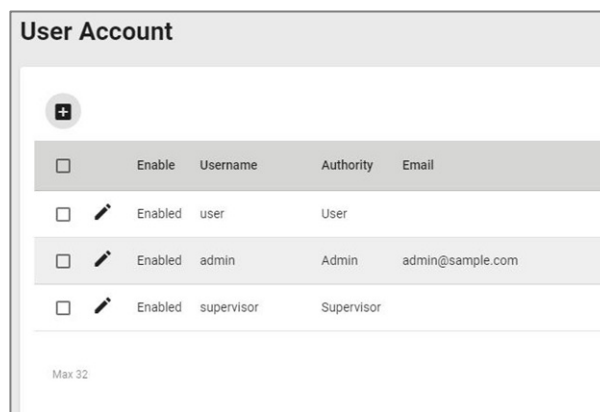

User Accounts

Menu Path: System > Account Management > User Accounts

This page lets you manage the user accounts for your device.

Note

By default, there is only one account: admin

UI Setting	Description
Enable	Shows whether the account is enabled or disabled.

UI Setting	Description
Username	Shows the username of the account.
Authority	Shows the authority level of the account.
Email	Shows the email address of the account.

User Accounts - Create a New Account

Menu Path: System > Account Management > User Accounts

Clicking the **Add (+)** icon on the **System > Account Management > User Accounts** page will open this dialog box. This dialog lets you create a new user account. Click **CREATE** to save your changes and add the new account.

User Accounts - Delete Account

Menu Path: System > Account Management > User Accounts

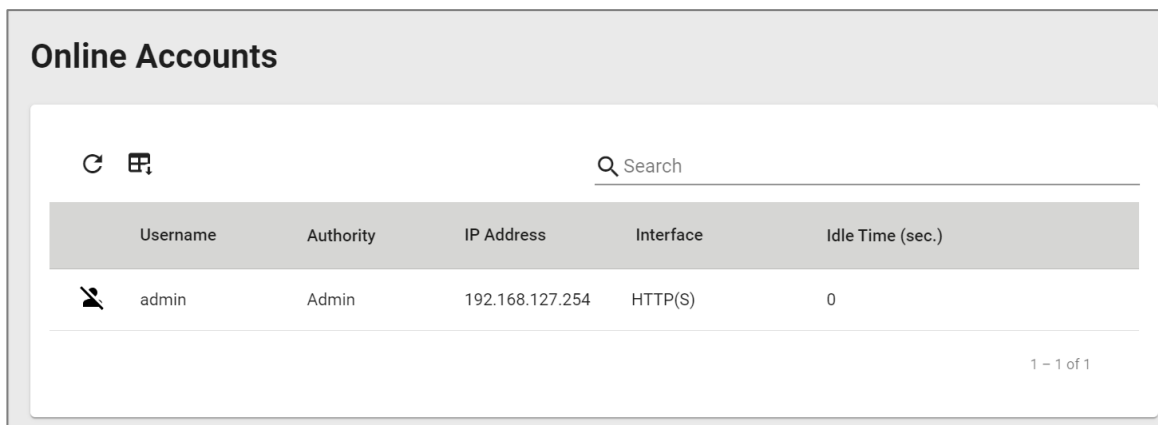

You can delete an account by using the checkboxes to select the entries you want to delete, then clicking the **Delete** (🗑️) icon.

Online Accounts

Menu Path: System > Account Management > Online Accounts

This page lets you view a list of connected user and also lets you disconnect users.

UI Setting	Description
Username	Shows the username of the online account.
Authority	Shows the authority level of the online account.
IP Address	Shows the IP address of the online account.
Interface	Shows the interface that the online account is using.
Idle Time (sec.)	Show the idle time in seconds for the online account.

Online Accounts - Remove This Online Account

Menu Path: System > Account Management > Online Accounts

You can disconnect a user by clicking its **Remove** () icon. Click **REMOVE** to save your changes and remove the online account.

Password Policy

Menu Path: System > Account Management > Password Policy

This page lets you create a robust password policy to safeguard your system against hackers. By enforcing minimum length and complexity requirements, you can empower users to choose strong passwords that are difficult to crack. Additionally, you can set a maximum password lifetime to ensure regular password changes, further enhancing security. Click **APPLY** to save your changes.

Note

To improve the security of your device and network, we recommend that you:

- Set the Minimum Length for passwords to 16
- Enable the Password complexity strength check and enable all the requirements
- Set a Maximum Password Lifetime to ensure that users change their password regularly

Minimum Password Length *

4

4 - 63

Maximum Password Lifetime *

0

0 - 365 day

Password Character Requirements

Password Character Requirements apply to IEEE 802.1x, SNMP Account, SNMP Trap/Inform Account and User Account.

Must contain at least one digit (0-9)

Must contain at least one uppercase letter (A-Z)

Must contain at least one lowercase letter (a-z)

Must contain at least one special character ({}[]()|:;~!@#%^*-_+=,.)

APPLY

UI Setting	Description	Valid Range	Default Value
Minimum Password Length	Specify the minimum required password length.	4 to 16 characters	4
Password Character Requirements	Select the complexity requirements that will apply to new passwords. <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p>Note</p> <p>New requirements will only apply when creating or changing a password. They will not apply to existing passwords.</p> </div>	Must contain at least one digit (0-9) / Must contain at least one uppercase letter (A-Z) / Must contain at least one lowercase letter (a-z) / Must contain at least one special character ({}[]() :;~!@#%^*-_+=,.)	N/A
Maximum Password Lifetime	Specify how long in days passwords will be valid for. When the password expires, the system will require the user to change their password. <p>If this is set to 0, passwords will not expire.</p>	0 to 365 days	0

Configuring Simple Network Management Protocol

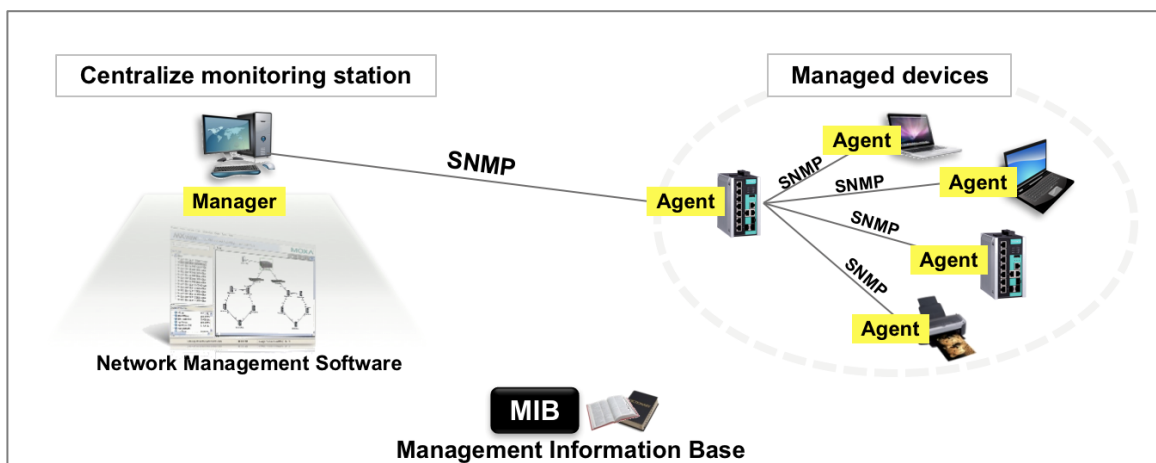

Simple Network Management Protocol (SNMP) be used to manage and monitor network devices.

It is an application-layer protocol that allows administrators to manage network performance, diagnose network problems, and gather information about network devices such as routers, switches, servers, printers, and other network equipment. SNMP works by using agents installed on network devices, which provide information to a central management system known as an SNMP manager. The manager sends requests to the agent to retrieve information about the device, such as CPU utilization, memory usage, network traffic, and other metrics.

About SNMP

An SNMP deployment consists of Managers, Agents, and Management Information Bases (MIBs).

- **Management Information Base (MIB):** A database of information about network devices and their performance metrics. The MIB is organized hierarchically and uses a tree-like structure.
- **SNMP Manager:** The central management system that monitors and manages network devices. It sends requests to the SNMP agents to gather information and configure network devices.
- **SNMP Agent:** A software module installed on network devices that provides information about the device to the SNMP manager. The agent responds to requests from the manager and sends notifications to the manager when certain events occur, such as a device failure.

SNMP agents expose management data on the managed systems as variables. The protocol also permits active management tasks, such as configuration changes, through remote modification of these variables. The variables accessible via SNMP are organized in hierarchies. SNMP itself does not define which variables a managed system should offer. Rather, SNMP uses an extensible design that allows applications to define their own hierarchies. These hierarchies are described as a management information base (MIB). MIBs describe the structure of the management data of a device subsystem; they use a hierarchical namespace containing object identifiers (OID). Each OID identifies a variable that can be read or set via SNMP.

Creating an SNMP Account

You must configure an SNMP account on each of your devices to manage them.

Some account settings are contingent on SNMP account settings. Protocol versions earlier than v3 do not support authentication or encryption, and require shared community keys. Go to **System > Management Interface > SNMP**, click **General**, and choose an SNMP Version. For insecure versions, also specify community strings.

Note

SNMP versions earlier than v3 do not support authentication or encryption, and provide no security. It is strongly recommended to choose V3 Only unless compatibility absolutely requires earlier versions and security risks have been thoroughly evaluated.

To configure SNMP accounts:

1. Sign in to the device using administrator credentials.
2. Go to **System > Management Interface > SNMP**, and then click **SNMP Account**.
3. Click  **[Add]**.

The Create an SNMP Account screen appears.

4. Specify all of the following, and then click **Create**:

Option	Value
Username	Specify a username for the account with up to 32 characters
Authority	Choose from: <ul style="list-style-type: none">• Read/Write• Read

Option	Value
Authentication Type	Choose from: <ul style="list-style-type: none"> • None • MD5 • SHA • SHA-256 • SHA-512 <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p> Note Authentication requires SNMP v3.</p> </div>
Authentication Password	If an authentication type has been specified, specify a password for the account between 8 and 64 characters long.
Encryption Key	<ul style="list-style-type: none"> • Disabled • DES • AES <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p> Note Encryption requires SNMP v3.</p> </div>
Encryption Key	If an encryption method has been chosen, specify an Encryption Key between 8 and 64 characters long.

The account appears in the **SNMP Account** table.

You can Edit or Delete from the list by clicking the corresponding  **[Edit]** or  **[Delete]**.

Deleting an SNMP Account

Menu Path: System > Management Interface > SNMP - SNMP Account

You can delete an account by clicking the **Delete** () icon next to the account.

Time

Menu Path: System > Time

This page lets you configure the time related settings.

This page includes these tabs:

- System Time
- NTP Server
- Time Synchronization

About System Time

Correct system time is required for automatic warning emails to include a time and date stamp.

Note

Make sure to update the Current Time and Current Date after the switch has been powered off for three days or more. This is particularly important when no NTP server or Internet connection are available.

This section describes how to configure the **System Time**, **NTP Server**, and **Time Synchronization** settings for the switch. The switch has a time calibration function based on information from an NTP server or a user-specified time and date, allowing functions such as automatic warning emails to include a time and date stamp.

Configuring System Time

To configure System Time, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **System > Time > System Time**, and then click on the **Time** tab.
3. Set **Clock Source** to **Enabled**.

4. Configure the **Date**, **Time**, and **Time Zone**. Specify **Daylight Savings** details if appropriate for your region.
5. Click **Apply** to save your settings.

System Time

Menu Path: [System](#) > [Time](#) > [System Time](#)

This page lets you configure the system time.

This page includes these tabs:

- Time
- NTP Authentication

System Time - Time

Menu Path: [System](#) > [Time](#) > [System Time - Time](#)

This page lets you configure your device's system time.

NTP Authentication

Menu Path: System > Time > System Time - NTP Authentication

This page lets you configure NTP authentication for when the device is acting as an NTP client. This helps ensure that received NTP responses are from the NTP server and have not been modified in transit.

Limitations

You can create up to 10 NTP authentication entries.

UI Setting	Description
Key ID	Shows the key ID for NTP authentication.
Type	Shows the authentication type.
Key String	Shows the password used for authentication.

Creating an NTP Authentication Entry

Menu Path: System > Time > System Time - NTP Authentication

Clicking the **Add (+)** icon on the **System > Time > System Time - NTP Authentication** page will open this dialog box. This dialog lets you create an NTP authentication entry.

Click **CREATE** to save your changes and add the new account.

UI Setting	Description	Valid Range	Default Value
Key ID	Specify the Key ID to use for NTP authentication.	1 to 65535	N/A
Type	Specify the authentication type.	MD5 / AES128CMAC	MD5
Key String	Specify the password to use for the authentication key.	0 to 32 characters	N/A

About NTP Servers

Network Time Protocol (NTP) is used to synchronize the clocks of computers and other devices on a network, and is widely used on the Internet and in local networks to ensure accurate timekeeping. NTP operates by exchanging time information between servers and clients.

NTP Servers In Depth

Typically, there are several hierarchical strata of NTP servers.

- **Stratum 1 servers** are directly connected to highly accurate time sources, such as atomic clocks or GPS receivers.
- **Stratum 2 servers** synchronize their time with Stratum 1 servers.
- **Client devices** synchronize their clocks with NTP servers, which helps maintain accurate time across the network.

You can configure your device to act as an NTP client to sync the system time with a specified NTP server.

You can also configure your device to act as an NTP server to provide time sync service to end devices on the network. When enabling the NTP server function, the device will answer the NTP queries sent from NTP client and provide the device's time to the client.

NTP Server

Menu Path: System > Time > NTP Server

This page lets you configure your device to act as an NTP server.

About Time Synchronization

Time synchronization aligns the clocks of different devices to the same time for fault-tolerant synchronization of real-time clocks.

Note

The IEEE 1588 working group now uses timeTransmitter and timeReceiver instead of "master" and "slave." This document adopts these terms.

Note

For MDS-G4000 Series and MDS-G4000-4XGS Series devices, if PTP must be used with multiple modules, slot M2 must be used for cross-module sync.

- Hot-swapping modules with PTP enabled may cause timing jitter.
- Hot-swapping the module in the M2 slot will remove the master clock, resulting in timing fluctuations.
- PTP will stay active when hot-swapping, but will resynchronize after the new module is inserted.

Precision Time Protocol (PTP) is a Time Synchronization protocol designed to synchronize clocks through Ethernet networks. The accuracy for IEEE 1588 PTP v2 can be measured in microseconds or nanoseconds.

This device supports the following IEEE 1588 profiles:

- **IEEE 1588 Default 2008** - The default protocol for industrial systems. Nanosecond-level accuracy.
- **IEC 61850-9-3-2016**: A profile of IEEE 1588 designed specifically for power system applications, such as digital substations and grid automation. Mandates additional requirements to ensure compliance with other power systems. Millisecond-level accuracy.
- **IEEE C37.238-2017**: A profile of IEEE 1588 designed for broader power system applications, such as for fault logging, real-time monitoring, and wider networks. Sub-microsecond accuracy.

PTP uses several roles for different clock roles, which dictate whether the device is a source or destination of time data:

- **GrandMaster**: Primary reference clock for network, usually with a precise time source, such as an atomic clock or satellite link.
- **timeTransmitter**: Receives time information from GrandMaster and distributes correct time further downstream.
- **timeReceiver**: Receives correct time from timeTransmitter. Usually only have a single network connection.

Clock roles are used across multiple clock types.

This device supports serving as following clock types:

- **Boundary Clock**: Synchronizes its internal clock to the Grandmaster, distributes time data to downstream clocks as timeTransmitter.
- **Transparent Clock**: Corrects PTP messages to include their own delay information, then relays further downstream. Does not synchronize its internal clock. Used for maintaining multiple layers of network devices.

Intermediate clock types support two clock modes:

- **One Step**: One step synchronization sends all time sync data in a single message, reducing overhead, but may require specialized hardware that supports inline time stamping.

- **Two Step:** Two step synchronization sends Follow_Up message to synchronize time information. This may generate additional latency, but is widely used by substations, and may be suitable for a wider range of networking devices.

Configuring Time Synchronization

Enable and configure Time Synchronization global settings before configuring individual ports.

1. Sign in to the device with administrator credentials.
2. Go to **System > Time > Time Synchronization**, and then click on the **General** tab.
3. To enable Time Synchronization, click **Time Synchronization**, and then choose **Enable** from the drop-down menu.
4. Configure the following:

Option	Value
Profile	Choose the time synchronization profile to use.
Clock type	Choose the clock type to use: Boundary Clock or Transparent Clock
Delay Mechanism	<p>For Profile: IEEE 1588 Default-2008, choose a delay mechanism to compensate for network delay between <code>timeTransmitter</code> and <code>timeReceiver</code>:</p> <ul style="list-style-type: none"> • End-to-End uses central delay requests and response between <code>timeTransmitter</code> and <code>timeReceiver</code>. Assumes symmetric delays. Does not require PTP-aware networking equipment, but may have reduced performance in large or congested networks. • Peer-to-Peer calculates delay at each network node. Requires PTP-aware networking equipment, but scales reliably and can accommodate asymmetric delays.
Transport Mode	For Profile: IEEE 1588 Default-2008 , choose a transport mode.
Priority 1	For Clock Type: Boundary Clock , specify priority value to override the default election method. Lower values take precedence. Default: 128

Option	Value
Priority 2	For Clock Type: Boundary Clock , specify a secondary priority value to serve as a tiebreaker in the event that two candidates match the default criteria. Default: 128
Domain Number	Specify a domain number, which allows multiple clock systems to share the same medium. Each GrandMaster clock should be in its own domain, with receiving clocks configured to match. The default domain is 0.
Clock Mode	Choose One Step or Two Step (default).
Accuracy Alert	Specify an accuracy alert threshold in nanoseconds. Exceeding this threshold sends an event notification. Default: 1000
Maximum Steps Removed	For Clock Type: Boundary Clock , specify the maximum number of steps before time synchronization packets will be dropped, prompting GrandMaster re-election. Default: 255
Grandmaster ID	For Profile: C37.238-2017 and Clock Type: Boundary Clock , specify the ID to use if this device becomes GrandMaster . Default: 255
BMCA Best Master Clock Algorithm	For Clock Type: Transparent Clock , choose whether to Enabled (default) or Disabled the Best Master Clock Algorithm. Disabling may be preferable for sensitive applications where there is a requirement to use a specific GrandMaster .

 **Note**

Only appears under Advanced Mode on some models.

5. Click **Apply** to save your settings.

Time Synchronization is now be enabled globally.

Continue to enable Time Synchronization on specific ports to make the feature fully operational.

Enabling Time Synchronization on Ports

Once Time Synchronization is enabled globally, you can configure which ports will support timing messages.

Make sure you have chosen a **Profile** under the **General** tab in **System > Time > Time Synchronization**.

1. Go to **System > Time > Time Synchronization**, and then click on the **Port Settings** tab.
2. Locate the corresponding port to configure, and then click  **[Edit]**.

The Edit Port Settings screen appears.

3. Set **Time Synchronization** to **Enabled**.
4. For **Profile: IEEE 1588 Default-2008** selected under the **General** tab, configure the following:

Option	Description and Guidance
Announce Interval	Choose how often the <code>timeTransmitter</code> sends Announce messages to advertise itself. Lower values result in faster detection of failures but increase network traffic. Higher values reduce traffic but may slow failover detection. Default: 1 (2 sec.)
Announce Receipt Timeout	Specify the number of missed Announce messages before assuming the <code>timeTransmitter</code> is lost and starts a re-election. Lower values detect failures quickly but may trigger unnecessary re-elections. Higher values allow more tolerance for occasional packet loss. Default: 3
Sync Interval	Choose how often Sync messages are sent by the <code>timeTransmitter</code> . More frequent updates improve precision but increase bandwidth usage. Less frequent updates reduce overhead but may lower accuracy. Default: 0 (1 sec.)
Delay-Request Interval	Choose a Peer-to-Peer (P2P) delay measurement, which determines how often delay request messages are sent. Lower intervals provide more frequent updates for dynamic networks. Higher values reduce network load but may impact precision. Default: -0 (1 sec.)

5. To apply your changes to more than one port, click **Copy configurations to ports**, and then select the ports to also use your settings.
6. Click **Apply** to save your changes.

Time Synchronization

Menu Path: [System](#) > [Time](#) > [Time Synchronization](#)

Configuring NTP Server

Moxa devices can serve as network time protocol (NTP) servers to allow other devices to synchronize their clocks over the network.

NTP operates by exchanging time information between servers and clients.

Typically, there are several hierarchical strata of NTP servers. Stratum 1 servers are directly connected to highly accurate time sources, such as atomic clocks or GPS receivers. Stratum 2 servers synchronize their time with Stratum 1 servers, and so on. Client devices synchronize their clocks with NTP servers, which helps maintain accurate time across the network.

NTP is widely used on the internet and in local networks to ensure accurate timekeeping, and it has been a critical component of network infrastructure for decades.

Our switch can act as NTP client to sync the system time with the configured NTP server (Stratum 1). Our switch can also act as an NTP server (Stratum 2) to propagate the synchronized time to other clients on the network.

Enabling NTP Server

1. Sign in to the device using administrator credentials.
2. Go to **System > Time > NTP Server**.
3. Set **NTP Server** to **Enabled**.
4. To Enable Client Authentication and create keys, do the following:
5. Set **Client Authentication** to **Enabled**.
6. Go to **System > Time > System Time > NTP Authentication**, and then click **Add**.

The **Create Entry** screen appears.

7. Key ID Type Key String Configure all of the following, and then click **Create**:

Option	Value
Key ID	Specify a number to identify the key
Type	Specify the authentication type.
Key String	Specify a key at least one character long.

MDI/MDIX	Shows the MDI/MDIX option used for the port.
Port State	Shows whether the port status is blocking or forwarding.

About Linkup Delay

Linkup delay, also known as link flap prevention, is used to prevent a port alternating between link up and link down statuses, and is useful when a link connection is unstable. An unstable connection might be caused by situations such as a faulty cable, faulty fiber transceiver, duplex mismatch, etc. Linkup delay helps you mitigate the risk of an unstable network, particularly when the topology changes frequently.

Linkup Delay

Menu Path: [Port](#) > [Port Interface](#) > [Linkup Delay](#)

This page lets you configure the linkup delay for device's ports.

Linkup Delay Settings

UI Setting	Description	Valid Range	Default Value
Linkup Delay	<p>Enable or disable the linkup delay feature for the device.</p> <div style="background-color: #f0f0f0; padding: 10px;"> <p> Note</p> <p>After enabling linkup delay, you will still need to configure and enable linkup delay for each port you want to use it on.</p> <p>Refer to Linkup Delay - Edit Port Settings for more information.</p> </div>	Enabled / Disabled	Disabled

Delay Time	Shows the delay time in seconds for the port.
Remaining Time	Shows the remaining time in seconds for the port to alternate between link up and link down.

Linkup Delay - Edit Port Settings

Menu Path: Port > Port Interface > Linkup Delay

To configure linkup delay for a port, click the **Edit** (✎) icon on the desired port on the **Port > Port Interface > Linkup Delay** page will open this dialog box. This dialog lets you configure the linkup delay parameters for the port.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
Linkup Delay	Enable or disable linkup delay for the port. Note To enable linkup delay for a port, both the linkup delay setting for the port and the global linkup delay setting must be enabled. Refer to Linkup Delay Settings for more information.	Enabled / Disabled	Disabled
Delay Time	Specify the delay time in seconds before the port alternates between link up and link down.	1 to 1000	2
Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

About Link Aggregation

Link aggregation, also known as port channels or port trunking, helps balance, optimize, and facilitate a device's throughput. This method combines multiple network communication interfaces in parallel to maximize data throughput, increasing data communication efficiency for each port. In addition, it also acts as a useful method for network redundancy when a link fails. In general, link aggregation supports combining multiple physical switch ports into a single, bandwidth-efficient data communication route. This can improve network load sharing and increase network reliability.

Static Trunk

For some networking applications, a situation can arise where traffic from multiple ports is required to be filtered through a single port. For example, if there are 30 UHD IP surveillance cameras deployed and connected in a ring, traffic can reach up to 1 Gbps, causing a surge in traffic that can increase network loading by up to 50%. Hence, the uplink port needs to use static trunking to provide additional bandwidth and redundancy protection.

LACP

Link Aggregation Control Protocol (LACP) is a protocol defined by IEEE 802.3ad that allows a network device to negotiate automatic bundling of several ports by sending LACP packets to the peer, a directly connected device that also uses LACP.

Link Aggregation Algorithms

In link aggregation, different load-sharing hash algorithms can be used to optimize packet forwarding:

- **SMAC:** Source MAC (SMAC) uses the source MAC address for a packet to optimize packet forwarding to ensure that packets from the same source address follow the same path consistently to optimize connection stability and reduce the chance of out-of-order packet delivery.
- **DMAC:** Destination MAC (DMAC) uses the destination MAC address for a packet to optimize packet forwarding to ensure that packets being sent to the same

destination address are consistently sent over the same link to optimize connection stability and traffic distribution.

- **SMAC + DMAC:** SMAC and DMAC can be used together for more complex hash algorithms, but tends to be used only when a network has few clients and servers.

Link Aggregation Settings

Menu Path: Port > Link Aggregation

This page lets you configure link aggregation groups for each port. A link aggregation group combines multiple physical ports into a single logical link.

🔒 Limitations

You can create up to 14 link aggregation groups.

Link Aggregation List

<input type="checkbox"/>	Port Channel (Trunk)	Enable	Type	Algorithm	Configure Member	Active Member
<input type="checkbox"/>	1	Enabled	Manual	SMAC + DMAC	1, 2	2
<input type="checkbox"/>	2	Enabled	LACP	SMAC + DMAC	3, 4	

Max. 10

UI Setting	Description
Port Channel (Trunk)	Shows the Port Channel (Trunk) number of the link aggregation group.
Enable	Shows whether the link aggregation group is enabled.
Type	Shows the method for configuring the link aggregation group.
Algorithm (Only in Advanced Mode)	Shows the load-sharing hash algorithms being used for the link aggregation group.
Configure Member	Shows the configured member ports in the link aggregation group.
Active Member	Shows the active member ports in the link aggregation group.

Creating a Link Aggregation Group

Menu Path: Port > Link Aggregation

Clicking the **Add (+)** icon on the **Port > Link Aggregation** page will open this dialog box. This dialog lets you create a link aggregation group.

Click **CREATE** to save your changes and add the new link aggregation group.

UI Setting	Description	Valid Range	Default Value
LA Group Status	Enable or disable the link aggregation group.	Enabled/ Disabled	Enabled
Type	Select the method to use for configuring the link aggregation group. Manual: This allows you to specify the ports to be included in the LA Group. LACP: LACP protocol will be used to automatically negotiate link aggregation configuration between devices.	Manual / LACP	N/A
Config Member Port	Select the ports to add to the link aggregation group. Note A port cannot be assigned to multiple link aggregation groups. This is because each port can only be a member of a single link aggregation group at a time. A link aggregation group (Port-channel) cannot be created when selected ports are operating at different speeds.	Device ports	N/A

UI Setting	Description	Valid Range	Default Value
Algorithm (Only in Advanced Mode)	Select the load-sharing hash algorithms to be used for configuring link aggregation.	SMAC / DMAC / SMAC+DMAC	SMAC+DMAC

Editing a Link Aggregation Group

Menu Path: Port > Link Aggregation

Clicking the **Edit** (✎) icon on the **Port > Link Aggregation** page will open this dialog box. This dialog lets you edit Link Aggregation group settings.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
LA Group Status	Enable or disable the link aggregation group.	Enabled/ Disabled	Enabled
Type	Select the method to use for configuring the link aggregation group. Manual: This allows you to specify the ports to be included in the LA Group. LACP: LACP protocol will be used to automatically negotiate link aggregation configuration between devices.	Manual / LACP	N/A

UI Setting	Description	Valid Range	Default Value

This is because each port can only be a member of a single link aggregation group at a time.</p> <p>A link aggregation group (Port-channel) cannot be created when selected ports are operating at different speeds.</p> </div>	Device ports	N/A
Algorithm (Only in Advanced Mode)	Select the load-sharing hash algorithms to be used for configuring link aggregation.	SMAC / DMAC / SMAC+DMAC	SMAC+DMAC

Deleting a Link Aggregation Group (Port Channel)

Menu Path: Port > Link Aggregation

You can delete a link aggregation group by using the checkboxes to select the entries you want to delete, then clicking the **Delete (🗑)** icon.

<input checked="" type="checkbox"/>	Port Channel (Trunk)	Enable	Type	Algorithm	Configure Member	Active Member
<input checked="" type="checkbox"/>	1	Enabled	LACP	SMAC + DMAC	1/2	

Link Aggregation - Port Settings for LACP

This table lets you see the LACP settings for each port.

Port	Mode	Timeout (sec.)	Wait Time (sec.)	Port Channel (Trunk)
 1	Active	90	2	1
 2	Active	90	2	1
 3	Active	90	2	2
 4	Active	90	2	2
 5	Active	90	2	
 6	Active	90	2	

UI Setting	Description
Port	Shows which port the entry describes.
Mode	Shows the LACP mode for the port.
Timeout (sec.)	Shows the LACP inactivity timeout in seconds for the port.
Wait Time (sec.)	Shows the LACP wait time in seconds for the port.
Port Channel (Trunk)	Shows the link aggregation group (Port channel) number for the port.

Editing Port Settings for LACP

Menu Path: Port > Link Aggregation

Clicking the **Edit** () icon by a port on the **Port > Link Aggregation** page will open this dialog box. This dialog lets you edit the port settings for LACP parameters if your link aggregation type is set to LACP.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
Port Channel (Trunk)	Shows the link aggregation group (Port channel) number of the port. This setting cannot be changed.	Port Channel Number	N/A
Mode	<p>Select the LACP mode to decide how the ports establish LACP links.</p> <ul style="list-style-type: none"> • Active: Ports will actively query link partners for LACP by sending LACP PDUs. If the partner is also LACP-enabled, the ports will establish an LACP link. • Passive: Ports can respond to LACP queries from active ports and passively establish LACP links. They will not initiate any LACP negotiation on their own. <p>For LACP to establish a link, at least one port for the link must use active mode. If both ports are passive, no LACP PDUs will be sent, and no link will be established.</p>	Active / Passive	Active
Timeout	Specify the LACP inactivity timeout in seconds. This is the amount of time that must elapse without receiving any LACP PDUs before a link is considered to have failed.	3 / 90	90
Wait Time	Specify the LACP wait time in seconds. This is the amount of time that must elapse after a LACP link comes up before it is added to the link aggregation group.	0 to 10	2
Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

About PoE

Power over Ethernet (PoE) provides power along with network connectivity to PoE network devices (PDs), allowing them to be powered and connected to the network using a single network cable. This can greatly simplify installation, maintenance, and troubleshooting of these PoE devices, especially when they are installed in areas that are difficult to reach or do not have power outlets nearby.

PoE is frequently used with a variety of devices:

- Surveillance cameras
- Security I/O sensors
- Industrial wireless access points
- Emergency IP phones

Moxa devices support high-power PoE+ and PoE++ standards as well as advanced PoE management functions such as PD failure check, legacy PD detection, and auto power cutting. These work together to provide critical security systems with a convenient and reliable Ethernet network that is easier to manage.

PoE Settings

Menu Path: [Port](#) > [PoE](#)

This page lets you configure your device's Power over Ethernet (PoE) settings. PoE allows your Moxa device to power other connected PoE Ethernet devices—such as security cameras, wireless access points, and sensors—through the Ethernet cable.

This page includes these tabs:

- General
- PD Failure Check
- Scheduling
- Status

 **Note**

PoE functionality is only available on specific PoE-enabled Moxa device models. Connected PoE devices must support the IEEE 802.3af/at/bt standard in order to use this feature, with a maximum of 90 W per port.

PoE - General

Menu Path: Port > PoE - General

This page lets you enable PoE power output and configure system-level PoE settings.

 **Note**

When the PoE function is activated, PoE-enabled ports should only be connected to standard/legacy powered devices.

If there is a need to connect non-powered devices to a PoE-enabled port, it is recommended to disable PoE for the port to prevent unnecessary PoE detection behavior.

PoE Settings

 **Note**

The module budget limit is fixed to:

- LM-7000H Series PoE modules: 120 watts
- RKS-G4028/G4028-L3 Series: 240 watts

PoE - System Status

System Status

Power Budget Limit	Module Budget Limit	Allocated Power	Consumed Power	Remaining Power Available	
0 Watts	240 Watts	0 Watts	0 Watts	0 Watts	

UI Setting	Description
Power Budget Limit	Shows the PoE power budget limit.
Module Budget Limit (for modular switches only)	Shows the PoE power budget limit per module.
Allocated Power	Shows the total allocated PoE power.
Consumed Power	Shows the total consumed PoE power.
Remaining Power Available	Shows the remaining power available for the device.

 **Note**

Remaining Power Available is Maximum Input Power minus Allocated Power.

PoE Status - Port List

 **Note**

When a higher-power 802.3bt (Class 5~8) PD is connected to a lower-power 802.3at or 802.3af PSE, the PD will simply operate at a lower power state, which is known as downgrading. In this case, the classification and the device type of the PD will appear as Class 4 and 802.3at because of inherent device limitations.

Note

For MDS-G4000 Series and MDS-G4000-4XGS Series devices, if the port is set to force mode, the classification of the PD will appear as Unknown.

Port	PoE Supported	Power Output	Classification	Current (mA)	Voltage (V)	Consumption (W)	Device Type	Configuration suggestion	PD Failure Check Status
1	Yes	Off	Unknown	0.00	0.00	0.00	N/A	Enable PoE power output	Not alive
2	Yes	Off	Unknown	0.00	0.00	0.00	N/A	Enable PoE power output	Not alive
3	Yes	Off	Unknown	0.00	0.00	0.00	N/A	Enable PoE power output	Not alive
4	Yes	Off	Unknown	0.00	0.00	0.00	N/A	Enable PoE power output	Not alive
5	Yes	Off	Unknown	0.00	0.00	0.00	N/A	Enable PoE power output	Not alive

UI Setting	Description
Port	Shows the number of the PoE port.
PoE Supported	Shows whether the port supports PoE.
Power Output	Shows whether PoE power output is on or off for the port.
Classification	<p>Shows the PoE power classification of the port.</p> <p>Each PoE power classification has a different maximum power (in watts) by PSE output as follows:</p> <ul style="list-style-type: none">• 0: 15.4 watts• 1: 4 watts• 2: 7 watts• 3: 15.4 watts• 4: 30 watts• 5: 45 watts• 6: 60 watts• 7: 75 watts• 8: 90 watts
Current (mA)	Shows the amount of current (in mA) being supplied to the port.
Voltage (V)	Shows the voltage (in V) being used for the port.
Consumption (W)	Shows the power consumption (in W) of the device connected to the port.

UI Setting	Description
Device Type	<p>Shows the device type of the device currently connected to the port.</p> <ul style="list-style-type: none"> • Not Present: There are no active connections to the port. • Legacy PoE Device: A legacy PD is connected to the port, and the device has detected that the voltage is too low or high, or the PD's detected capacitance is too high. • 802.3bt: An IEEE 802.3bt PD is connected to the port. • 802.3at: An IEEE 802.3at PD is connected to the port. • 802.3af: An IEEE 802.3af PD is connected to the port. • NIC: A NIC is connected to the port. • Unknown: An unknown PD is connected to the port. • N/A: The PoE function is disabled.
Configuration Suggestion	<p>Shows configuration suggestions based on detected conditions.</p> <ul style="list-style-type: none"> • Disable PoE power output: A NIC or unknown PD was detected; you may want to disable PoE power output for the port. • Select Force Mode: A higher/lower resistance or higher capacitance was detected; you may want to select Force Mode for the port. • Select high power output: An unknown classification was detected; you may want to select High Power output. • Raise the external power supply voltage to greater than 46 VDC: When the external supply voltage is detected at less than 46 V, the system suggests raising the voltage. • Enable PoE function for detection: The system suggests enabling the PoE function. • Select IEEE 802.3bt auto mode: When detecting an IEEE 802.3bt PD, the system suggests selecting 802.3bt Auto mode. • Select IEEE 802.3at auto mode: When detecting an IEEE 802.3at PD, the system suggests selecting 802.3at Auto mode. • Select IEEE 802.3af auto mode: When detecting an IEEE 802.3af PD, the system suggests selecting 802.3af Auto mode.

About VLAN

A VLAN, or Virtual Local Area Network, is a logical grouping of devices on a network.

Assigning VLANs to Ports

VLANs must be assigned to ports to route traffic correctly. Now that you've created the VLANs, they need to be assigned to ports so that traffic from those ports will be routed over the correct VLAN. A similar procedure must be performed on each switch or router on the network.

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching**→**VLAN**→**Settings**.
3. To assign the newly created VLAN ID to a port, find the port on the **Port Table** on the lower part of the page, and then click  **[Edit]**.

Result: The **Edit Port Settings** panel appears.

4. Specify the **Mode** and **PVID** that will be assigned to the port, and then click **Apply**.

Tutorial Info:

Access mode is used when connecting single devices without tags. These are usually end-user devices that belong to a single VLAN, and do not need to communicate with devices in other VLANs.

Trunk mode allows a port to carry traffic for multiple VLANs over a single physical connection. This is useful for linking switches together that may have many different VLANs.

Hybrid mode is similar to a Trunk port, except users can explicitly assign tags to be removed from egress packets.

 **Note**

The port VID (PVID) setting will apply a VLAN tag only for untagged traffic coming through that port. If traffic going through the port has already been tagged with a VLAN ID, the PVID setting will not change the existing tag.

Result: The **Port Table** will show the new port configuration.

Creating VLANs

Create VLANs in preparation for assigning them to ports.

To create a VLAN, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching > VLAN > Settings**.
3. To add a VLAN ID, click  **[Add]**.

Result: The **Create VLAN** screen appears.

4. Specify the VLAN to create in the **VID**, and then click **Create**.

Optionally:

- Type a human-readable identifier in the **Name** field
- Assign the VLAN to a **Member Port**. You also assign VLANs to ports later.

Result: The VLAN will appear on the VLAN table at the top of the page.

5. Repeat this process to create VLANs needed for the network topology.

What to do next: After you have created the VLANs needed for your topology, you can assign VLANs to ports if you have not done so already.

 **Note**

You can delete VLANs by choosing a VLAN ID from the VLAN table at the top of the page, clicking the checkbox, and then clicking  [Delete].

VLANs in Depth

This technology allows network administrators to divide a large network into smaller, more manageable segments without the need for additional physical hardware. Devices within a VLAN can be located anywhere on the network but communicate as though they are on the same physical segment. This facilitates traffic management, as administrators can ensure traffic is directed only to devices within the same VLAN by assigning a VLAN tag to each Ethernet frame. Consequently, VLANs provide a means to segment a network beyond the constraints of physical connections, a limitation inherent in traditional network design. VLANs can be utilized to segment your network into various groups, such as:

- **Departmental groups**—One VLAN for the R&D department, another for Office Automation, etc.
- **Hierarchical groups**—One VLAN for directors, another for managers, and another for general staff.
- **Usage groups**—One VLAN for email users and another for multimedia users.

VLAN Standards and Implementation

The functioning of VLANs is guided by IEEE 802.1Q, often referred to as Dot1q. This standard outlines the protocol for VLAN tagging on Ethernet frames within an IEEE 802.3 Ethernet network. During the transmission of data between switches, VLAN tags identify the VLAN ownership of frames. Networking equipment reads these tags and ensures that tagged frames are delivered to devices within that VLAN, maintaining the network's logical segmentation.

A VLAN tag is a specific piece of data embedded in the header of an Ethernet frame. It comprises a 4-byte field carrying key information, such as the VLAN ID (VID) and priority level. The VID is a numerical identifier that uniquely links the frame to a specific VLAN. The priority field within the tag plays a critical role in prioritizing certain types of traffic within a VLAN. This structure contributes to effective network traffic management by giving precedence to certain data when necessary.

Benefits of VLANs

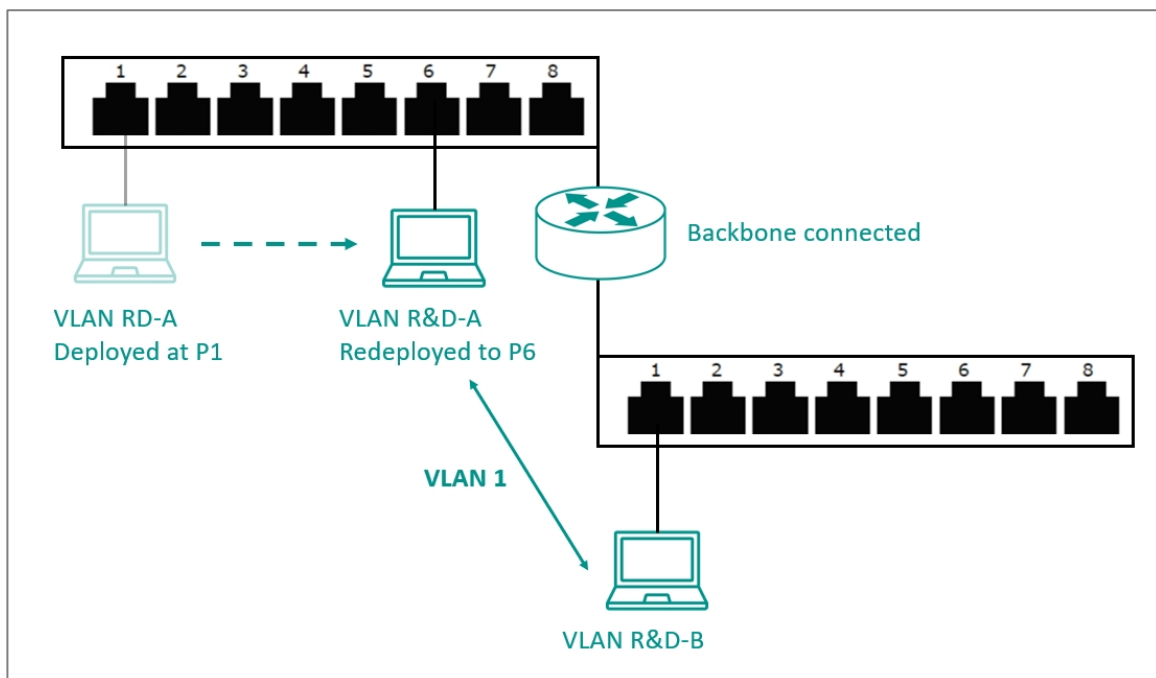

The main benefit of VLANs is that they provide a network segmentation system that is far more flexible than traditional networks. Using VLANs also provides you with three other benefits:

VLANS help control traffic

With traditional networks, congestion can be caused by broadcast traffic that is directed to all network devices, regardless of whether or not they need it. VLANs increase the efficiency of your network because each VLAN can be set up to contain only those devices that need to communicate with each other.

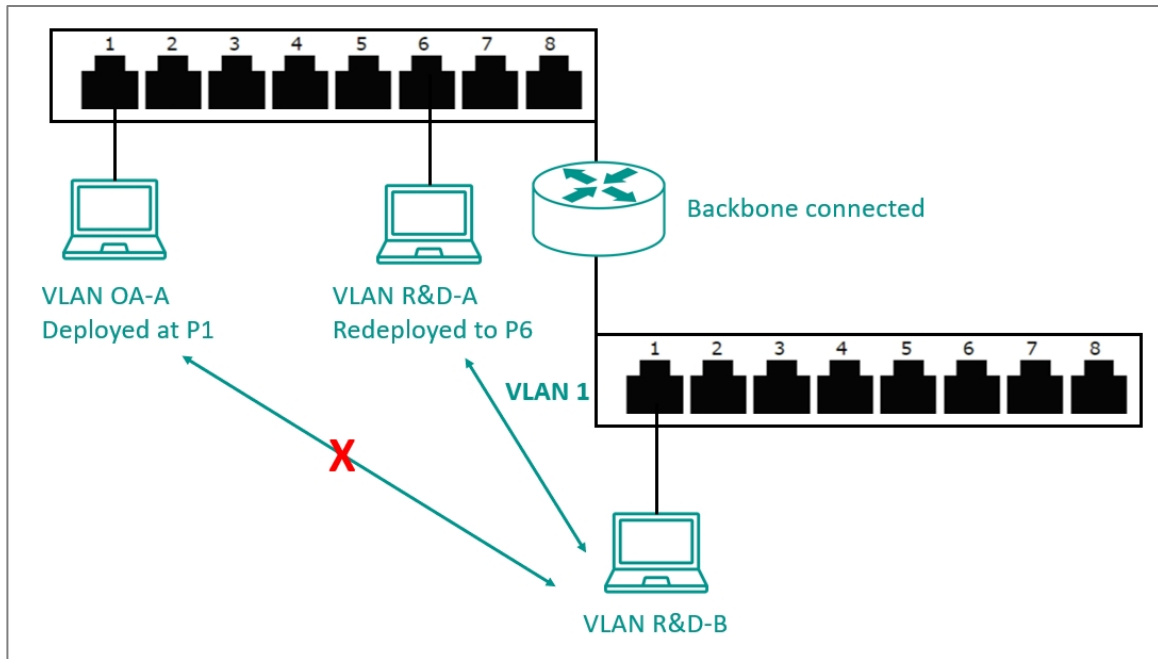

VLANS simplify device relocation

In traditional networks, administrators spend significant time managing moves and changes, requiring manual updates of host addresses when users switch sub-networks. In contrast, VLANs simplify this process. For example, when relocating a host from Port 1 to Port 6 in a different network section, simply assign Port 6 to the relevant VLAN (e.g., VLAN R&D A). This enables seamless communication between VLANs, eliminating the need for re-cabling.

VLANS provide extra security

Devices within each VLAN can only communicate with other devices on the same VLAN. If VLAN R&D B needs to communicate with VLAN OA(Office Automation) A, the traffic must pass through a routing device or Layer 3 switch.

Note

Network segmentation is not a substitute for network security. While network segmentation can provide a degree of isolation that contributes to the overall security environment, the primary benefit of VLANs is improved performance by ensuring minimal crosstalk between unrelated systems. Network segmentation should be complimented with network security procedures.

VLAN Settings

Menu Path: Layer 2 Switching > VLAN

This page lets you view and configure your device's VLAN settings.

This page includes these tabs:

- Global
- Settings
- Status

VLAN - Global

Menu Path: Layer 2 Switching > VLAN - Global

This page lets you configure the global VLAN settings.

VLAN Settings

GVRP *

Disabled ▾

APPLY

UI Setting	Description	Valid Range	Default Value
GVRP	Enable or disable GVRP for the device. Note MSTP and GVRP are both VLAN-related functions. When VLAN changes dynamically, MSTP needs to re-converge, which can make the system unstable due to running complex operations. When both MSTP and GVRP are used together, this can result in network instability. Therefore, it is recommended that network administrators avoid enabling both MSTP and GVRP.	Enabled / Disabled	Disabled

VLAN - Settings

Menu Path: Layer 2 Switching > VLAN - Settings

This page lets you configure VLANs and which ports they include.

Limitations

You can create up to 512 VLAN IDs.

VLAN List

VLAN ID	Name	Member Port	Forbidden Port
1		1, 2, 3, 6, 7, 8, 9, 10, 14, 15, 16, G1, G3, G4, G5, G6, G7, G8	
4	LAN4	4, po1	
5	LAN5	5, G2	
11	Trunk1		
13	LAN13	13	

UI Setting	Description
VLAN ID	Shows the ID of the VLAN.
Name	Shows the name of the VLAN.
Member Port	Shows the member port(s) of the VLAN.
Forbidden Port	Shows the forbidden port(s) of the VLAN.

VLAN - Create VLAN

Menu Path: Layer 2 Switching > VLAN - Settings

Clicking the **Add (+)** icon for port on the **Layer 2 Switching > VLAN - Settings** page will open this dialog box. This dialog lets you create a VLAN.

Click **CREATE** to save your changes.

GARP

Generic Attribute Registration Protocol (GARP) is a communication protocol defined by IEEE 802.1 that offers a generic framework for bridges to register and de-register an attribute value.

In a VLAN structure, two GARP applications can be applied:

- **GARP VLAN Registration Protocol (GVRP)** is used to register VLAN trunking between multilayer switches.
- **GARP Multicast Registration Protocol (GMRP)** provides a constrained multicast flooding facility.

GARP Settings

MAC Address	Specify the static unicast MAC address of the port.	Valid unicast MAC address	N/A
Port	Specify which ports you want to include in the static unicast group	Drop-down list of ports	N/A

About MAC Address Tables

The MAC address table is a database maintained on your device that acts like a directory to keep track of all the devices currently connected to the network. Each entry in the table includes a device's unique identifier, known as its Media Access Control (MAC) address, and the specific switch port it is connected to.

Note

Moxa devices manage MAC address learning for VLANs using IVL (Independent VLAN Learning), which uses separate MAC address tables for each VLAN so that MAC address learning for different VLANs do not interfere with each other.

A MAC table will be stored in the format of MAC + VID. This allows the same MAC address to be used in multiple VLANs without causing forwarding issues.

This may lead to a larger MAC address table size, as each VLAN maintains its own individual address table, and the number of MAC address entries will increase based on the number of VLAN member ports used.

MAC Address Table

Menu Path: Layer 2 Switching > MAC > MAC Address Table

This page lets you view your device's MAC address table and set the aging time for MAC address entries.

Limitations

The MAC address table can hold up to 16384 entries.

MAC Address Settings

UI Setting	Description	Valid Range	Default Value
MAC Learning Mode	Shows the current MAC learning mode.	N/A	Independent VLAN Learning

UI Setting	Description	Valid Range	Default Value
Aging Time	Specify the aging time for MAC address entries in seconds. The aging time determines how long entries will be kept in the MAC address table in the device's memory before expiring.	10 to 300	300

Click APPLY to save your changes.

MAC Address Table List

Index	VLAN ID	MAC Address	Type	Port
1	1	00:90:E8:A9:ED:2B	Learnt Unicast	2

Max. 16384

UI Setting	Description
Index	Shows the index number of the MAC address.
VLAN ID	Shows which VLAN ID is being used for the MAC address.
MAC Address	Shows the MAC address of the device.
Type	Shows what kind of MAC address entry this is: Learnt Unicast: Used for all learnt unicast MAC addresses. Learnt Multicast: Used for all learnt multicast MAC addresses. Static Unicast: Used for all static unicast MAC addresses. Static Multicast: Used for all static multicast MAC addresses.
Port	Shows which port on the device the MAC address is connected to.

About QoS

Quality of Service (QoS) is a set of techniques and mechanisms used in computer networks to prioritize certain types of traffic to ensure reliable delivery of data and optimize network performance. QoS mechanisms allow network administrators to define

policies and rules for managing network resources and controlling the flow of traffic based on factors such as traffic type and application requirements.

This device has the following QoS features:

- Classification
- Ingress Rate Limit
- Scheduler
- Egress Shaper

QoS In Depth

This device provides Quality of Service (QoS) for your network by classifying and prioritizing traffic to make data delivery more reliable. Traffic can be classified by applying IEEE 802.1p/1Q Layer 2 CoS (Class of Service) tags or Layer 3 DSCP (Differentiated Services Code Point) information. The device can use these together with a set of rules that specify how each type of traffic should be treated as it passes through the device. This allows delivery of traffic to be prioritized to ensure that high-priority data is transmitted with minimum delay. Refer to Classification for more information about traffic classification.

Two scheduling algorithms, Strict Priority and Weighted Round Robin, are available to empower network administrators to choose the most suitable method for packet transmission in their field applications. Refer to Scheduler for more information.

In addition to packet classification for incoming packets and scheduling for outgoing packets, users can also establish a rate threshold for incoming data. When this limit is exceeded, they can choose to either drop or remark the packet. Refer to Ingress Rate Limit for more information.

The egress shaper helps optimize outbound traffic, maintain network stability, and ensure efficient utilization of available bandwidth resources. Refer to Egress Shaper for more information.

QoS

Menu Path: Layer 2 Switching > QoS

This section lets you enable and configure your device's QoS settings.

This section includes these pages:

- Classification
- Ingress Rate Limit
- Scheduler
- Egress Shaper

 **Note**

For MX-NOS platform devices, QoS behavior will be consistent as long as the chipset solutions are the same. Therefore, RKS/MDS/TN devices will exhibit identical QoS behavior.

Classification

Traffic classification and prioritization allows you to classify data for prioritization so that time-sensitive and system-critical data can be transferred smoothly and with minimal delay over a network.

Benefits of using traffic classification and prioritization include:

- Improving network performance by controlling a wide variety of traffic types and managing congestion
- Assigning priorities to different categories of traffic, such as setting higher priorities for time-critical or mission-critical applications
- Providing predictable throughput to improve the performance of multimedia applications—such as video conferencing or voice over IP—to minimize traffic delay and jitter
- Optimizing network utilization depending on application usage and usage needs, allowing the amount of traffic to increase without requiring increases in backbone bandwidth

Traffic classification and prioritization uses eight traffic queues to ensure that higher priority traffic can be forwarded separately from lower priority traffic to help guarantee quality of service (QoS) for your network.

Traffic classification and prioritization for your Moxa device is based on two standards:

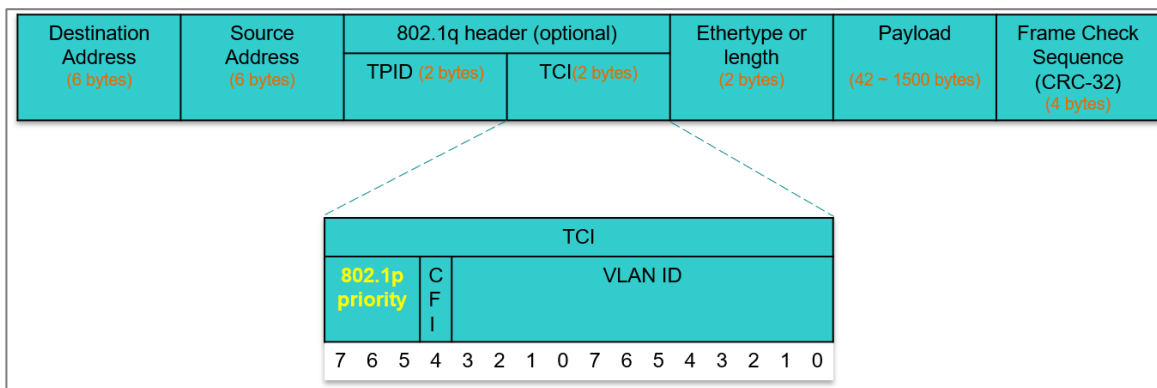

- **IEEE 802.1p Class of Service:** A Layer 2 QoS marking scheme

- **Differentiated Services (DiffServ) Traffic Marking:** A Layer 3 QoS marking scheme

IEEE 802.1p Class of Service (CoS) In Depth

The IEEE Std 802.1D 2005 Edition marking scheme, which is an enhancement to IEEE Std 802.1D, enables Quality of Service on a LAN. Traffic service levels are defined in the IEEE 802.1Q 4-byte tag, which is used to carry VLAN identification as well as IEEE 802.1p priority information. If the 802.1q header presents and the Tag Protocol Identifier (TPID) value is 0x8100, then it means the frame is tagged. The TPID is followed by a 2-byte field Tag Control Information (TCI) which contains a 3-bit 802.1p priority field as shown in below figure.

The IEEE Std 802.1D 2005 Edition priority marking scheme assigns an IEEE 802.1p priority level between 0 and 7 to each frame, which specifies the level of service that the associated packets shall be handled.

The table below shows an example of how different traffic types can be mapped to the eight IEEE 802.1p priority levels.

IEEE 802.1p Priority (decimal)	IEEE 802.1p Priority (binary)	IEEE 802.1D Traffic Type
0	0 0 0	Best Effort
1	0 0 1	Background (lowest priority)
2	0 1 0	Reserved
3	0 1 1	Excellent Effort (business critical)

IEEE 802.1p Priority (decimal)	IEEE 802.1p Priority (binary)	IEEE 802.1D Traffic Type
4	1 0 0	Controlled Load (streaming multimedia)
5	1 0 1	Video (interactive media)
6	1 1 0	Voice (interactive voice)
7	1 1 1	Network Control Reserved traffic

Even though the IEEE 802.1p standard is the most widely used prioritization scheme for LAN environments, it still has some restrictions:

- It requires an additional 4-byte tag in the frame, which is normally optional for Ethernet networks. Without this tag, the scheme cannot work.
- The tag is part of the IEEE 802.1Q header, so to implement QoS at Layer 2, the entire network must implement IEEE 802.1Q VLAN tagging.
- It is only supported within a LAN and does not cross the WAN boundaries, since the IEEE 802.1Q tags will be removed when the packets pass through a router.

Differentiated Services (DiffServ) Traffic Marking In Depth

DiffServ is a Layer 3 marking scheme that uses the DiffServ Code Point (DSCP) field in the IP header to specify the packet priority. DSCP is an intelligent method of traffic marking that allows you to choose how your network prioritizes different types of traffic. The DSCP field can be set from 0 to 63 to map to user-defined service levels, enabling users to regulate and categorize traffic by application and assign different service levels.

Advantages of DiffServ over IEEE 802.1Q

- You can prioritize and assign different traffic with appropriate latency, throughput, or reliability for each port.
- No extra tags are required.
- The DSCP priority tags are carried in the IP header, which can pass through WAN boundaries and through the Internet.
- DSCP is backwards compatible with IPv4 ToS (Type of Service), which allows operation with legacy devices that use IPv4 Layer 3.

Default Mapping of DSCP and CoS Values

DSCP values	Mapped CoS value
0 to 7	0
8 to 15	1
16 to 23	2
24 to 31	3
32 to 39	4
40 to 47	5
48 to 55	6
56 to 63	7

Traffic Prioritization In Depth

Moxa switches classify traffic based on Layer 2 of the OSI 7 layer model, and prioritize outbound traffic according to the priority information defined in received packets. Incoming traffic is classified based on the IEEE 802.1p service level field and is assigned to the appropriate egress priority queue.

Traffic flows through the switch as follows:

- A received packet may or may not have an 802.1p tag associated with it. If it does not, then it is given a default CoS value according to the port settings in the Classification section.
- Each egress queue has associated 802.1p priority levels that can be defined by users. Packets will be placed in the appropriate priority queue. When the packet reaches the head of its queue and is about to be transmitted, the device determines whether or not the egress port belongs to the VLAN group. If it is, then the new 802.1p tag is used in the extended 802.1D header.

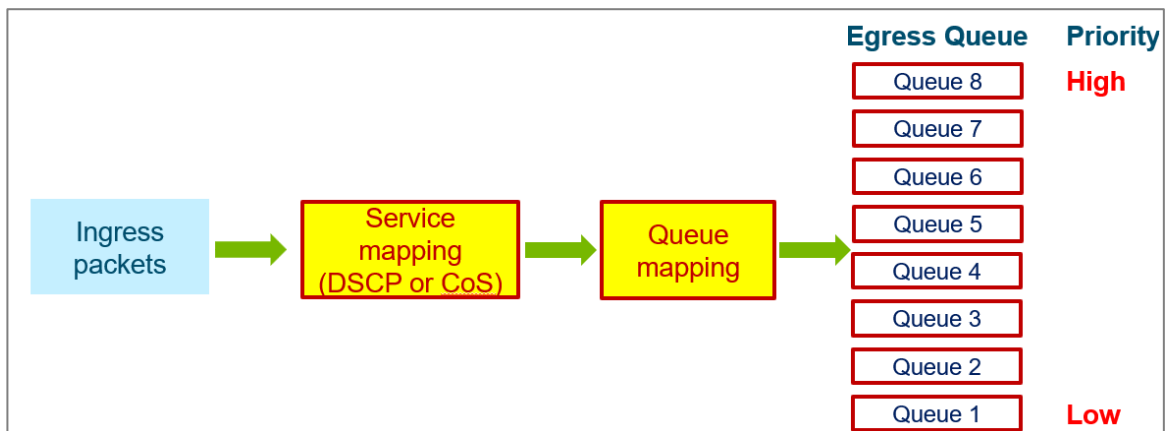

Please be aware that the priority of redundancy protocol control packets is determined by the switch and is not influenced by user-specified QoS settings. The prioritization of

traffic is determined by the QoS policies configured on network devices, and remains consistent regardless of whether the interface used is a single port or a trunk port.

Traffic Queues In Depth

Moxa switches have eight different traffic queues that allow packet prioritization to occur. The priority of these queues ranges from 1 (lowest priority) to 8 (highest priority). Higher priority traffic can pass through the switch without being delayed by lower priority traffic.

Ingress packets containing DSCP or CoS fields require classification and mapping to a priority queue. Incoming packets with a specified DSCP value at Layer 3 are remapped to a CoS value at Layer 2 before being directed to an egress queue. The corresponding mapping of DSCP to CoS and the CoS to the egress queue priority should be preconfigured on a Moxa switch. As each packet arrives at the switch, it undergoes ingress processing (which includes classification, marking/re-marking), and is then sorted into the appropriate egress queue.

Packets lacking DSCP or CoS values will be directed to the appropriate egress queue based on the settings of Untag Default Priority configured in Port Settings. Refer to Port Classification - Edit Port Setting for more information.

About Ingress Rate Limits

Ingress rate limits drop—or "mark"—network traffic when it exceeds user-defined thresholds.

Ingress Rate Limits In-depth

There are two elements to this process:

- Meter - An algorithm in the switch that monitors and limits traffic by applying QoS markers to data packets or dropping them entirely
- Marker - The DSCP/802.1p field of data packets is assigned a value or "marked" by the QoS policies, determining their handling in the network

Meter algorithms include simple token bucket and SrTCM (Single Rate Three Color Marker) (RFC2697).

In addition to ingress rate management, the switch also offers an option for the administrators to configure the shutdown of an Ethernet port that may be under attack from an excess of incoming packets, such as a Denial-of-Service attack.

About Port Shutdown

Ports can be shutdown to avoid broadcast storms.

In general, any user shall not consume unlimited bandwidth and influence others' access. One particular scenario is that a malfunctioning switch or mis-configured network might cause "broadcast storms". Moxa industrial Ethernet switches not only prevent broadcast storms, but can also regulate ingress packet rates, giving administrators full control of their limited bandwidth to prevent undesirable effects caused by unpredictable faults.

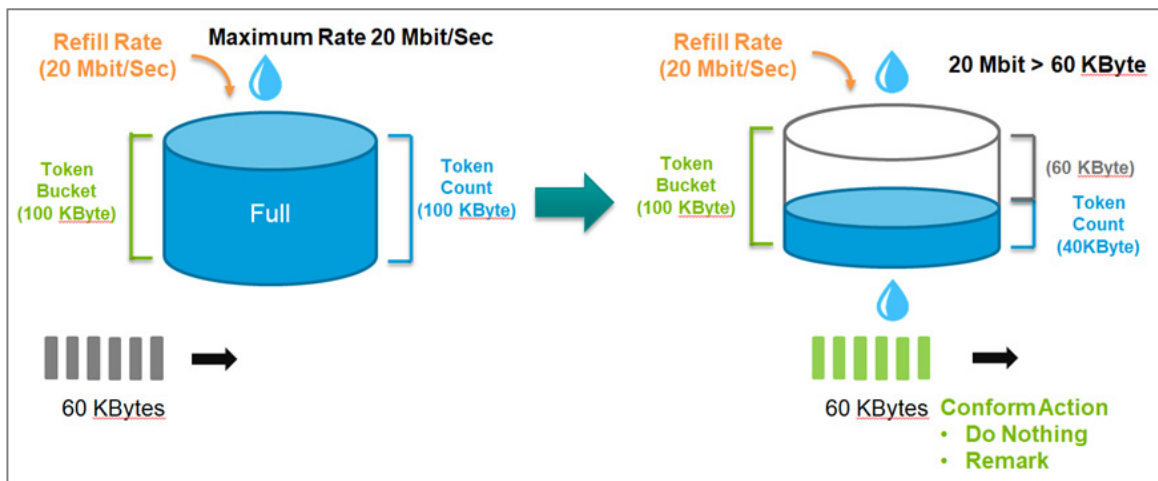

The network administrator has the option to establish a maximum throughput threshold (in Mbps) for incoming packets on a designated port and activate this function. If unexpected ingress packets are detected on that port, the physical Ethernet port will be disabled, preventing further packet transmission. Re-activation of the port can be done manually or left to occur automatically after the pre-defined release interval, specified in minutes, has elapsed.

About Token Buckets

Token Bucket is an algorithm used to achieve an efficient network flow control and manage bandwidth. This algorithm is based on a token bucket that allows for a traffic surge for short periods. When a token is unavailable, no burst of packets can be sent. Under this concept, the number of tokens will be refilled in the bucket at specific intervals. Users need to configure these settings so that the tokens in the bucket are always available to ensure packets can be sent when necessary.

CAR (Committed Access Rate) is a traffic control mechanism used to ensure that packets meet the network rules before they enter the network. CAR can guarantee the traffic flow is under user-defined control; the packets exceeding the rule will be either dropped or remarked and transmitted again. When network traffic is jammed, these packets will be dropped first.

Token Bucket is an algorithm that is demonstrated as a container in the image below. The token can be seen as a marker to mark a packet that is allowed to be transmitted through this switch. When the token is flowing into the bucket, the length of the bucket will be consumed as the volume of the bucket is limited. When the volume of the bucket is insufficient, some packets will be dropped or remarked and transmitted again. This

algorithm can control the speed of the traffic flow by consuming the speed of the token in the bucket.

About Single Rate Three Color Markers

Single Rate Three Color Markers (SrTCM) is a policing scheme for ingress rate limits. Traffic marking is based on a Committed Information Rate (CIR) and two associated burst sizes:

- Committed Burst Size (CBS)
- Excess Burst Size (EBS)

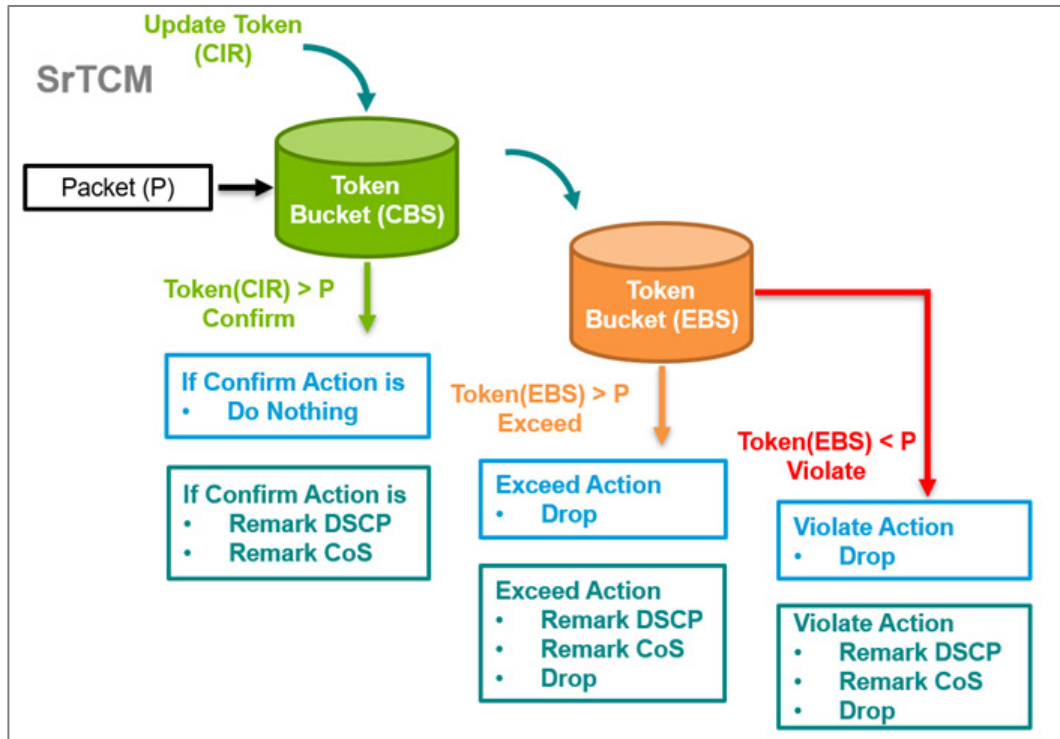

A packet is marked green if it does not exceed the CBS, yellow if it does exceed the CBS, but not the EBS, and red otherwise.

SrTCM will categorize the ingress packet by its length, and mark it as one of three colors:

- **Green:** performs the "conform" action. It could be "Do nothing", "Remark DSCP" or "Remark CoS". The Token Bucket (CBS) will deduct corresponding tokens.
- **Yellow:** performs the "exceed" action. It could be "Drop", "Remark DSCP" or "Remark CoS". The Token Bucket (EBS) will deduct corresponding tokens.
- **Red:** performs the "violate" action. It could be "Drop", "Remark DSCP" or "Remark CoS".

If you select "Do nothing" as the conform action, then "Drop" will be the only action when it enters the Exceed or Violate state.

The SrTCM is useful for ingress policing of a service, where only the length, not the peak rate, of the burst determines service eligibility.

Dropping Limit-exceeding Incoming Packets

You can setup the ingress rate limits that will automatically drop packets exceeding limits you specify.

In this example, we will prevent the switch from being overwhelmed by unexpected large amount of ingress packets through port 1, set an ingress rate limit of 5 Mbps on port 1. Then, verify that the device connected to port 2 receives packets at no more than 5 Mbps.

Before you begin:

- Change the configuration mode to **Advanced** mode by selecting the mode in the upper right corner of the UI.
 - Create a new **VLAN ID** with a value of **10**
 - Configure Port 1 with a **PVID** of 10 and with **Access mode** enabled
 - Configure Port 2 with a **PVID** of 10 and with **Access mode** enabled
1. Sign in to the device using administrator credentials.
 2. Go to **Layer 2 Switching**→**QoS**→**Ingress Rate Limit**→**General**.

3. Click **[Edit]** corresponding to **Port 1**.
Result: The **Edit Port Settings** dialogue appears.

4. In the **Ingress Rate (CIR)** field, specify 5 Mbps, and then click **Apply**.
Result: The new Ingress Rate (CIR) will appear in the table.

Results:

When a device connected to port 1 sends out a large number of packets (for example, at a rate exceeding 10 Mbps), the switch will throttle the incoming packets to match the configured limit (5 Mbps in this example) before forwarding them to port 2.

Remarking Limit-exceeding Incoming Packets

Abstract:

Short Description: You can setup the ingress rate limits that will automatically remark packets exceeding limits you specify.

In this example, we will limit incoming packets to 5 Mbps on Port 1—maintaining a consistent ingress rate. To avoid dropping data caused by a sudden influx of packets from Port 1, the outgoing packets will be remarked with a DSCP value (0x07) before sending over Port 2.

Before you begin:

- Change the configuration mode to **Advanced** mode by selecting the mode in the upper right corner of the UI.
- Create a new **VLAN ID** with a value of **10**
- Configure Port 1 with a **PVID** of 10 and with **Access mode** enabled
- Configure Port 2 with a **PVID** of 10 and with **Access mode** enabled

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching**→**QoS**→**Ingress Rate Limit**→**General**.
3. Click **[Edit]** corresponding to **Port 1**.
Result: The **Edit Port Settings** dialogue appears.

4. Specify the following:

Value	Option
Type	Simple Token Bucket
Ingress Rate (CIR)	5 Mbps
Conform Action	Remark DSCP
Conform Action > Remark Value	0
Violate Action	Remark DSCP
Violate Action > Remark Value	7

5. Click **Apply** to save changes.

Results:

When a device connected to port 1 sends out a large number of packets (for example, at a rate exceeding 10 Mbps), the switch will throttle the incoming packets to match the configured limit (5 Mbps in this example) and remark DSCP value (0x07) without dropping the packets. This ensures the timely transmission of data to the device connected on port 2.

UI Setting	Description
Port	Shows the port number for the entry.
Type	Shows the ingress limit type for the port.
Ingress Rate (CIR)	Shows the ingress Committed Information Rate (CIR) value for the port.
CBS	Shows the ingress Committed Burst Size (CBS) value for the port.
EBS	Shows the ingress Excess Burst Size (EBS) value for the port.
Mode	Shows the meter mode for the port. <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p> Note Currently, only color-blind mode is supported for metering.</p> </div>
Conform Action	Shows the conform action for the port.
Exceed Action	Shows the exceed action for the port.
Violate Action	Shows the violate action for the port.

Ingress Rate Limit - Edit Port Settings

Menu Path: Layer 2 Switching > QoS > Ingress Rate Limit - General

Clicking the **Edit** (✎) icon for a port on the **Layer 2 Switching > QoS > Ingress Rate Limit - General** page will open this dialog box. This dialog lets you select the traffic policy and configure associated actions for specific conditions on a per-port basis.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
Type	Specify the ingress limit type to use.	Simple Token Bucket / SrTCM	Simple Token Bucket
Ingress Rate (CIR)	Specify the maximum bandwidth allowed for ingress through the port in Mbps.	1 to 1000	100 for Fast Ethernet ports, 1000 for Gigabit Ethernet ports

UI Setting	Description	Valid Range	Default Value
CBS (Committed Burst Size)	Specify the data buffer size in KB for the port that can be used when the data rate exceeds the CIR rate. Data that exceeds the CIR rate will be saved in this buffer, and will be sent when bandwidth is available.	0 to 10240	1024
EBS (Excess Burst Size) (if Type is SrTCM)	Specify the data buffer size in KB for the port when the data rate exceeds the CIR rate. Data that exceeds the CIR rate will be saved in the CBS buffer, and if the CBS buffer is full, data will be stored in the EBS buffer and will be sent when bandwidth is available.	0 to 10240	1024
Conform Action	Select a conform action for the port to take. If Remark CoS or Remark DSCP is selected, an additional input field will appear where a Remark value must be specified.	Do Nothing / Remark CoS / Remark DSCP	Do Nothing
Exceed Action (if Type is SrTCM)	Select an action to take if the amount of data exceeds both the CBS and EBS buffers. <ul style="list-style-type: none"> Drop: Packets marked as yellow will be dropped. Remark CoS: Specify a CoS Remark value to use if a packet is marked as yellow. This is only available if Remark CoS is selected for the Conform Action. Remark DSCP: Specify a DSCP Remark value to use if a packet is marked as yellow. This is only available if Remark DSCP is selected for the Conform Action. 	Drop / Remark CoS / Remark DSCP	Drop
Violate Action	Select an action to take if a packet violates CIR and CBS. <ul style="list-style-type: none"> Drop: Packets marked as violated will be dropped. Remark CoS: Specify a CoS Remark value to use if a packet is marked as violated. This is only available if Remark CoS is selected for the Conform Action. Remark DSCP: Specify a DSCP Remark value to use if a packet is marked as violated. This is only available if Remark DSCP is selected for the Conform Action. 	Drop / Remark CoS / Remark DSCP	Drop

About Scheduler

The Scheduler functions as an arbiter within the switching forwarding paths, prioritizing traffic flows based on user-defined criteria. This mechanism enhances data transmission efficiency and ensures that critical packets are transmitted with priority. Moxa devices support two scheduling algorithms: Strict Priority and Weighted Round Robin.

- **Weighted Round Robin:** The Weighted Round Robin type allows users to give priority to specific packets in the higher weighted queue to ensure those packets will be sent first. Moxa switches now have 8 queues, and the weights from highest to lowest are 8:8:4:4:2:2:1:1.
- **Strict:** The Strict Priority type allows users to determine to transmit packets in the highest priority queue first, while packets with lower priority will be transmitted later. This guarantees that traffic with the highest level of priority for data transmission will go first.

Moxa network devices are equipped with multiple traffic queues that enable packet prioritization. This allows higher-priority traffic to pass through the network devices without being delayed by lower-priority traffic. As each packet enters the network devices, it undergoes ingress processing, including classification and marking/re-marking, before being placed into the appropriate egress queue. The network device then forwards packets based on their assigned queue.

Scenario: Configuring 3 Devices with Strict Priority

In this scenario, we will configure three attached devices on the network device with strict priority.

Specifically, we will focus on how packets are managed as they leave (egress) the network device on a particular port. In this case, the setup involves three devices:

- **Device A:** Connected to port 1 on the network device.
- **Device B:** Connected to port 2 on the network device.
- **Device C:** Connected to port 3 on the network device.

Objective

The goal is to configure a "Strict Priority" scheduler on port 3 of the switch. This scheduler will control how packets are prioritized when they exit the switch from this port (which is connected to Device C).

Key Components

1. **DSCP (Differentiated Services Code Point) Value:**
 - This is a field in the IP header that indicates the level of priority a packet should have.
 - In this scenario, packets from Device A have a DSCP value of 0x48, which signifies they should be treated with higher priority.
2. **Egress Queues:**
 - Network switches typically have multiple egress queues per port. Each queue can be assigned different levels of priority.
 - In this case, queue 7 is configured as a high-priority queue, while queue 1 is a lower-priority queue.

Configuration Details

- **Device A (port 1)** is sending packets with a DSCP value of 0x48. These packets are mapped to egress queue 7 on port 3. Queue 7 is given a higher priority.
- **Device B (port 2)** is sending normal packets without any special DSCP value, so these packets are mapped to egress queue 1 on port 3. Queue 1 has a lower priority.

"Strict Priority" Scheduler

- **Strict Priority Scheduling** is a mechanism used to determine how packets are sent out when multiple queues have packets waiting to be transmitted.

- In a strict priority setup, the switch will always service higher-priority queues first. This means that as long as there are packets in queue 7 (the high-priority queue), they will be sent out before any packets in queue 1 (the lower-priority queue) are even considered.

Expected Behavior

- When **Device A** and **Device B** both send packets to **Device C** at the same time:
 - Packets from **Device A** (with DSCP 0x48) will be placed in the high-priority egress queue 7 and will be transmitted first.
 - Packets from **Device B** will be placed in the low-priority egress queue 1. These packets will only be transmitted once queue 7 is empty.
- As a result, packets from **Device A** will reach **Device C** quickly, without being delayed by the packets from **Device B**.

Summary

By configuring the scheduler with "Strict Priority" on port 3, we're ensuring that high-priority traffic (from Device A) is not delayed by lower-priority traffic (from Device B). This setup is crucial in scenarios where certain types of data, such as real-time communications or critical control signals, must be delivered promptly without delay.

Example: Configuring A Sample Environment for Strict Priority Scheduler (RKS-G4000_Series)

The QoS scheduler example relies on this configuration.

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching > VLAN > Settings**, and then click  **[Add]**.

The Create VLAN screen appears.

3. In **VLAN**, type 10, and then click **Create**.

The specified VLAN appears in the list.

4. In the table on the second half of the page, find **1/1** and click  **[Edit]**.

The Edit Port Settings screen appears.

5. Specify **Mode** as **Access**, and then specify a **PVID** of **10**.
6. Under **Copy configurations to ports**, choose ports **1/2** and **1/3**, and then click **Apply** to save changes.
7. Go to **Layer 2 Switching > QoS > Classification**, and under **DSCP Mapping**, locate **DSCP 48** and verify that it is set to **6**.

If the value is different, click  **[Edit]**, set **CoS Priority** to **6**, and then click **Apply**.

8. Click **CoS Mapping** at the top of the screen, locate **CoS 6**, and verify that **Queue** is set to **7**.

If the value is different, click  **[Edit]**, set **Queue** to **7**, and then click **Apply**.

The device on Port **1/3** needs to be configured to set its outgoing packets with a QoS DSCP value of 0x48.

Example: Configuring Scheduler for Strict Priority

Strict Priority switching ensures that higher priority packets always preempt loc

This example assumes the following configuration, outlined in the preceding section:

- VLAN of 10
- Ports **1/1**, **1/2**, and **1/3** in **Access** mode assigned to **PVID 10**
- **DSCP 48** set to **6**
- **CoS 6** with a **Queue** of **7**

Additionally, the device on Port **1/3** needs to be configured to set its outgoing packets with a QoS DSCP value of 0x48.

If your environment does not match the above configuration, the example may not function properly.

1. Sign in to the devices using administrator credentials.
2. Go to **Layer 2 Switching > QoS > Scheduler**.
3. Locate Port **1/3**, and then click  **[Edit]**.

The Edit Port Settings screen appears.

4. Make sure **Type** is set to **Strict Priority**, and then click **Apply**.

Configuring Egress Shaper

A shaper for egress traffic buffers or queues excess traffic to hold packets and shape traffic flow when source data rates are higher than expected.

About Egress Shaper

The Egress Shaper uses a meter algorithm known as a leaky bucket. Like its physical counterpart, the leaky bucket collects incoming traffic up to a maximum capacity. Data stored in the bucket is released at a steady rate. When the bucket is empty, the flow stops.

If incoming packets would exceed the capacity the bucket, those packets would be non-conforming, and are not added to the bucket (dropped). Data will be added to the bucket as space becomes available for conforming packets. To setup Egress Shaper on a specific port, you will need to provide CIR (Committed Information Rate) and CBS (Committed Burst Rate) values.

Configuring Rate Limits for Outgoing Traffic

You can use egress rate limits to ensure steady flow of traffic to ports you specify. In this scenario, we have 3 devices:

- Device A, connected to the switch at Port 1

- Device B, connected to the switch at Port 2
- Device C, connected to the switch at Port 3

When both Device A and Device B send packets simultaneously to Device C, and there are no rate limits set on ports 1 and 2, Configuring the Committed Information Rate (CIR) to 5 Mbps on port 3 ensures that the outgoing packets maintain a steady packet rate to reach Device C as expected.

Before you begin:

- Change the configuration mode to **Advanced** mode by selecting the mode in the upper right corner of the UI.
 - Create a new **VLAN ID** with a value of **10**
 - Configure Port 1 with a **PVID** of 10 and with **Access mode** enabled
 - Configure Port 2 with a **PVID** of 10 and with **Access mode** enabled
 - Configure Port 3 with a **PVID** of 10 and with **Access mode** enabled
1. Sign in to the device using administrator credentials.
 2. Go to **Layer 2 Switching > QoS > Egress Shaper**.
 3. Click  **[Edit]** corresponding to **Port 3**.
Result: The **Edit Port Settings** dialogue appears.
 4. In the **CIR** field, specify 5 Mbps, and then click **Apply**.
Result: The new Egress Rate (CIR) will appear in the table.

Multicast

Multicast is a one-to-many communication method that sends data to a specific group of receivers. Those who wish to receive multicast packets must register for the multicast service; unregistered recipients will not receive the packets. Multicast is an "on-demand" service typically used for audio and video applications. For example, IP cameras (commonly used in CCTV systems) may need to transmit video streams to three different security guard rooms in a building simultaneously. Multicast is also used for protocol exchanges, as L3 protocols (VRRP, OSPF, RIP, etc) communicate with each other using multicast.

Benefits of Multicast:

- **Efficient bandwidth utilization:** Multicast reduces network congestion by sending data to only interested recipients.
- **Reduced server load:** Multicast servers only need to send data once, rather than multiple times for individual recipients.
- **Scalability:** Multicast can effectively handle large groups of receivers without affecting network performance.

Overall, multicast is a valuable tool for efficient and scalable one-to-many communication, particularly in applications involving audio, video, and protocol exchanges.

Multicast In Depth

As mentioned, multicast is a network communication method designed for efficient one-to-many data transmission. Imagine you have a presentation you want to deliver to a specific group of people in a large conference hall. Instead of emailing it to everyone individually, multicast allows you to send it to a single "group" that only the intended recipients can access.

Here's a breakdown of how it works:

- **Groups and Membership:**
 - Devices interested in receiving the same data stream form a multicast group identified by a unique multicast address.

- Devices join or leave the group dynamically using protocols like IGMP (Internet Group Management Protocol).
- **Source and Data:**
 - A single source device transmits the data (e.g., a video stream, a software update).
 - The data is encapsulated with the specific multicast address of the target group.
- **Network Routing:**
 - Network switches and routers play a crucial role in directing the data.
 - They recognize the multicast address and replicate the data packet only for the ports connected to devices that are members of the target group.
 - Devices not in the group will not receive the data, reducing unnecessary network traffic.

There are three primary methods for controlling multicast traffic on a switch:

- **Static multicast** is for configuring the multicast forwarding entries in the switch in a manual or predetermined manner. (e.g., forward 01:00:5E:05:06:07 to ports 1, 2, and 3). This method suits static networks where you want to control all the multicast flow. Another scenario is that the end device cannot communicate with IGMP protocol.
- **GMRP** allows bridges and the devices at the edge of the network to perform dynamic group membership information registration with the MAC bridges connected to the same LAN section. This method lets bridges communicate with each other to register the static multicast table dynamically.
- **IGMP snooping** allows a device to listen in on the IGMP conversation between hosts and routers. By listening to these conversations, the device maintains an association mapping table between port(s) and multicast groups. This method suits dynamic networks where end devices use IGMP to register the multicast group.

In summary, here are key considerations when selecting a multicast traffic control method:

- For static networks with predetermined multicast destinations, **static multicast** offers a simple solution.

- If you have a network with multiple bridges and static multicast tables on edge devices, **GMRP** can help maintain consistency.
- In dynamic networks where end devices use IGMP, **IGMP snooping** provides efficient management of multicast traffic.

Multicast

Menu Path: Layer 2 Switching > Multicast

This section lets you configure the Multicast settings.

This section includes these pages:

- IGMP Snooping
- GMRP
- Static Multicast

About IGMP Snooping

IGMP snooping allows switches to reduce the amount of unwanted multicast traffic on a network by maintaining maps of multicast group members, ensuring that multicast packets are only delivered to devices that have explicitly asked to receive them. Internet Group Management Protocol (IGMP) is a network protocol that hosts nearby routers on networks to construct multicast group memberships. IGMP snooping allows a network switch to listen in on the IGMP conversation between hosts and routers. By listening to these conversations, the switch maintains an association mapping table between port(s) and multicast group.

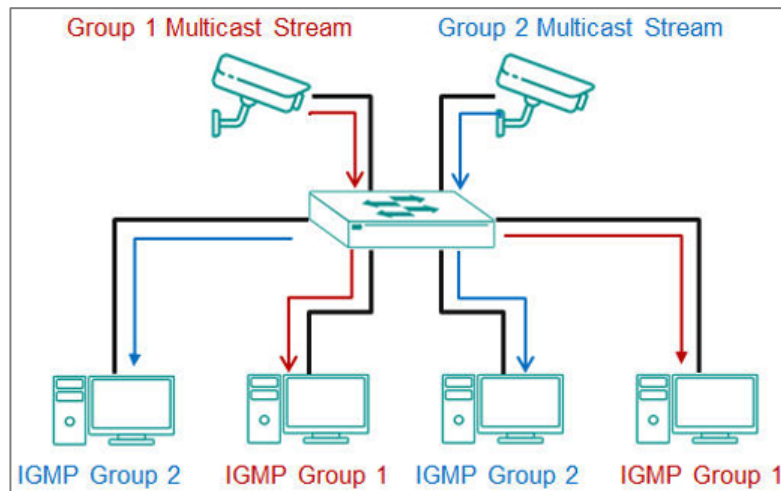

How IGMP Snooping Works

Without IGMP snooping, a switch will flood multicast traffic to all other non-ingress ports within a broadcast domain (or VLAN). This can cause unnecessary loading for host devices by requiring them to process packets they have not solicited. IGMP snooping can help prevent host devices on a local network from receiving traffic for a multicast group they have not explicitly joined. It provides switches with a mechanism to forward multicast traffic to specific ports that receive IGMP hosts, resulting in more efficient network bandwidth utilization.

Without IGMP Snooping:

With IGMP Snooping:

Enabling IGMP Snooping

IGMP Snooping must be enabled before it can be configured on specific interfaces.

To enable IGMP snooping, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching > Multicast > IGMP Snooping** and click **General**.
3. Set **IGMP Snooping** to **Enabled**.
4. Click **Apply**.

IGMP snooping is now enabled. Existing IGMP snooping configurations will now be active.

Configuring IGMP Snooping

IGMP snooping is configured at the VLAN level.

- VLAN IDs must be created and assigned before IGMP snooping can be configured.
- IGMP Snooping must be enabled before it can be configured on specific interfaces.

To configure IGMP snooping, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching > Multicast > IGMP Snooping**, and click **VLAN Settings**.

The **IGMP Snooping** list of **VLAN IDs** appears.

3. Click  **[Edit]** corresponding to the VLANs on which to configure IGMP snooping.

Note: If you do not see the VLANs you expect, make sure they are correctly assigned.

The Edit VLAN Settings screen appears.

4. Configure all of the following:

Option	Value
IGMP Snooping	Enabled
Version	Choose a version corresponding to device support and feature needs.
Query Interval	125
Static Router Port	This is optional.
Config Role	Querier

5. Click **Apply**.

About IGMP Versions

IGMP protocols regulate the communication mechanism between querier and listener.

For IGMP-related settings, ensure that you have chosen the correct protocol version.

Consult the table below for guidelines on choosing a version.

IGMP Version	Features	Reference
v1	<p>Features:</p> <ul style="list-style-type: none"> • Multicast Group Membership: Host devices can join multicast groups, but there is no explicit leave message. The host will simply stop responding to membership queries. • Membership Query: Network devices periodically send membership queries to determine if any host devices are still interested in receiving multicast traffic. • Membership Report: When a host device wants to join a multicast group, it sends a membership report. If no reports are received for a multicast group, the network device assumes there are no interested hosts and stops forwarding traffic to that group. <p>Limitations: No Leave Group Message: Hosts cannot explicitly leave a multicast group, which can lead to inefficient use of resources as routers have to rely on timeouts to determine if there are no more members.</p>	RFC-1112
v2	<p>Additional features:</p> <ul style="list-style-type: none"> • Leave Group Message: Host devices can send a leave group message to notify the network device they are no longer interested in a multicast group, improving the efficiency of multicast traffic management. • Group-Specific Queries: Network devices can send group-specific queries to confirm if any members of a particular multicast group still exist, reducing overall network traffic compared to general queries. • Query Election: Introduces a mechanism to elect a single query router on a subnet to avoid redundant queries, thereby optimizing network bandwidth. 	RFC-2236
v3	<p>Additional Features:</p> <ul style="list-style-type: none"> • Source-Specific Multicast (SSM): Supports source filtering, allowing host devices to specify from which sources they receive multicast traffic. This is useful for applications that need to filter out unwanted traffic from certain sources. • Include/Exclude Mode: Host devices can explicitly include or exclude traffic from specified sources, providing more granular control over multicast group membership. • Membership Report Enhancements: The membership report format is enhanced to support the new source filtering capabilities. 	RFC-3376

Note

Although most modern devices should support v3, there may be regulatory concerns or legacy deployments to consider.

IGMP Snooping

Menu Path: Layer 2 Switching > Multicast > IGMP Snooping

This page lets you configure IGMP snooping for your device.

This page includes these tabs:

About GMRP

GMRP stands for GARP Multicast Registration Protocol, which is a Generic Attribute Registration Protocol (GARP) application that can be used to prevent multicast from data flooding.

Both GMRP and GARP are defined by IEEE 802.1P, and widely used as a standard protocol in various industrial-related applications. GMRP allows bridges and the devices at the edge of the network to perform a dynamic group membership information registration with the MAC bridges connected to the same LAN section. The information can be transmitted among all bridges in the Bridge LAN that is implemented with extended filtering features. To operate GMRP, the GARP service must be established first.

GARP stands for **Generic Attribute Registration Protocol**, which is a communication protocol defined by IEEE 802.1, offering a generic framework for bridges to register and de-register an attribute value. In a LAN structure, two applications can be applied: **GARP VLAN Registration Protocol (GVRP)** is used to register VLAN trunking between multilayer switches, and **GARP Multicast Registration Protocol (GMRP)** for providing a constrained multicast flooding facility.

L2 switches exchange GMRP packets with each other to know the multicast entries on other switches so that it can also register the multicast entry on its own table. After exchanging the information, the multicast traffic will only be forwarded to the corresponding ports.

Configuring GMRP

1. Sign in to the device using administrator credentials.
2. Go to **Layer 2 Switching > Multicast > GMRP**.
3. Set **GMRP** to **Enabled**, and then click **Apply**.
4. Locate the port on which you want to enable GMRP, and then click the corresponding  **[Edit]** button.

The Edit Port Settings screen appears.

5. Set **GMRP** to **Enabled**, and then click **Apply** to save your settings.

GMRP is now enabled.

About Static Multicast

Static multicast is for configuring the multicast forwarding entries in the switch in a manual or predetermined manner.

In multicast networking, data packets are sent from one sender to multiple receivers efficiently, rather than sending individual packets to each receiver separately, as in unicast communication.

Network administrators manually configure the multicast forwarding entries in the device's multicast forwarding table. This involves specifying the multicast group addresses and the corresponding outbound interfaces or ports through which multicast traffic should be forwarded.

Benefits:

1. **Predictable Behavior:** Static multicast provides predictable behavior, as the forwarding paths for multicast traffic are predetermined by the administrator. This can be advantageous in certain network environments where stability and control are prioritized over flexibility and adaptability.
2. **Resource Efficiency:** Since static multicast entries are manually configured and do not involve the overhead of dynamic routing protocols, they can be more resource-efficient in terms of processing power and network bandwidth, especially in small-scale deployments with relatively stable multicast group memberships.

How Static Multicast works

If the user wants to restrict some of the multicast groups to be forwarded to specific ports for devices that don't support IGMP, users can use static multicast setting.

Users can manually register the multicast forwarding entries, including multicast MAC address and forwarding/forbidden port on the table, and the switch will forward the multicast traffic following the table rather than flooding.

Static Multicast

Menu Path: Layer 2 Switching > Multicast > Static Multicast

This page lets you view and manage your device's static multicast table.

About Spanning Tree

The Spanning Tree Protocol (STP) was designed to help construct a loop-free logical topology on an Ethernet network and provide an automatic means of avoiding any network loops. This is particularly important for networks that have a complicated architecture, since unintended loops in the network can cause broadcast storms. Moxa switches' STP feature is disabled by default. To be completely effective, you must enable STP/RSTP on every Moxa switch connected to your network.

STP (802.1D) is a bridge-based system that is used to implement parallel paths for network traffic. STP uses a loop-detection process to:

- Locate and then disable less efficient paths (e.g., paths that have lower bandwidth).
- Enable one of the less efficient paths if a more efficient path fails.

Rapid Spanning Tree Protocol (RSTP) is an IEEE 802.1w network protocol that enhances the speed and stability of the Spanning Tree Protocol (STP). RSTP promotes high availability and a "loop-free" topology, similar to STP, but more quickly within Ethernet networks. It provides faster convergence and is backward compatible with STP. While STP takes 30-50 seconds to converge, RSTP can achieve sub-second convergence.

For applications that require redundancy, but require use of only open-standard protocols and no proprietary protocols, RSTP is a good choice.

Difference Between STP and RSTP

RSTP is similar to STP but includes additional information in the BPDUs that allow each bridge to confirm that it has taken action to prevent loops from forming when it decides to enable a link to a neighboring bridge. Adjacent bridges connected via point-to-point links will be able to enable a link without waiting to ensure that all other bridges in the network have had time to react to the change. The main benefit of RSTP is that the configuration decision is made locally rather than network-wide, allowing RSTP to carry out automatic configuration and restore a link faster than STP.

STP and RSTP spanning tree protocols operate without regard to a network's VLAN configuration and maintain one common spanning tree throughout a bridged network. Thus, these protocols map one loop-free, logical topology on a given physical topology.

About BPDU Guard

About BPDU Guard

BDPUs (Bridge Protocol Data Units) are the network communication frames used in the STP (Spanning Tree Protocol). When two switches exchange messages, BDPUs are used to calculate the STP topology, and determine the network communication route. A BPDU filter is often used to screen sending or receiving BDPUs on a specific port of the switch.

BPDU Guard is a protection mechanism that prevents a port from receiving BDPUs. When an RSTP-enabled port receives BDPUs, it will automatically be in the error-disable state, which means the port will in turn switch to Block state. When STP is enabled, all ports are involved in the STP domain, sending and receiving BDPUs. However, when BPDU Guard is enabled, all ports will not receive or send any BDPUs, as all computers and unmanaged switches do not support STP. When BPDU Guard is enabled, all

communications will be treated as error-disabled, and the related ports will be blocked, therefore no more data will be sent or received, protecting the network from a loop chain.

- **Root Guard:** Root Guard prevents a designated port role from changing to root port role on reception of superior information.
- **Loop Guard:** Loop Guard prevents temporary loops in a network caused by **non-designated ports** changing to the spanning-tree **forwarding** state due to a link failure in the topology.
- **BPDU Filter:** BPDU Filter prevents a port from sending and processing BPDUs. A BPDU filter enabled port cannot transmit any BPDUs and drop all received BPDUs either.

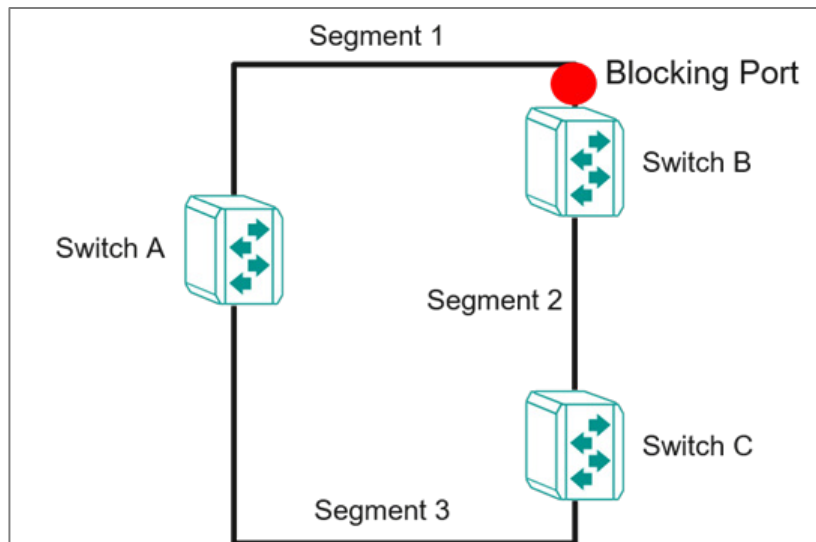

About STP Operations

The figure below shows a network made up of three LANs separated by three bridges. Each segment uses at most two paths to communicate with the other segments. Since this configuration can give rise to loops, the network will overload if STP is not enabled.

If STP is enabled, it will detect duplicate paths or block one of the paths from forwarding traffic. In the following example, STP determined that traffic from segment 2 to segment

1 flows through switches C and A since this path is in a forwarding state and is processing BPDUs. However, switch B on segment 1 is in a blocking state.

What happens if a link failure is detected? As shown in the figure below, the STP will change the blocking state to a forwarding state so that traffic from segment 2 flows through switch B to segment 1 through a redundant path.

STP will determine which path between each segment is most efficient, and then assign a specific reference point on the network. When the most efficient path has been identified, the other paths are blocked. In the previous three figures, STP first determined that the path through switch C was the most efficient, and as a result, blocked the path through

switch B. After the failure of switch C, STP re-evaluated the situation and opened the path through switch B.

About RSTP

Rapid Spanning Tree Protocol (RSTP) is an enhancement of the original Spanning Tree Protocol (STP) designed to speed up network convergence and improve overall network performance. RSTP ensures there is only one active path between devices in a network, with backup paths ready to activate if the primary path fails.

Each port is assigned a cost that indicates the efficiency of its link. Typically, this cost is determined by the link's bandwidth, with less efficient links assigned a higher cost.

The RSTP path cost default was originally calculated after detecting the bandwidth as follows.

Link Speed	RSTP/MSTP cost
100 Mbit/s	200,000
1 Gbit/s	20,000
10 Gbit/s	2,000

This can be overwritten from the UI.

Key Features of RSTP

- **Faster Convergence:** RSTP reduces the time required to detect and respond to network topology changes compared to STP. It eliminates the lengthy listening and learning states of STP, allowing for quicker transitions to active states.
- **Localized Decision-Making:** Unlike STP, where decisions are made network-wide, RSTP enables switches to make local configuration decisions. This allows for faster automatic configuration and quicker restoration of network links.
- **Simplified Port Roles:** RSTP uses only three primary port roles—Root Port, Designated Port, and Alternate Port—streamlining the network's operation and improving convergence speed.

- **Proposal/Agreement Mechanism:** RSTP introduces the Proposal/Agreement process to quickly determine designated ports during topology changes, further accelerating convergence.

How RSTP Works

RSTP operates in the following sequence:

1. **Root Bridge Selection:** The switch with the lowest bridge priority or MAC address is designated as the root bridge, forming the base of the spanning tree.
2. **Root Port Selection:** Non-root switches select their root port, which provides the best path to the root bridge based on path cost.
3. **Designated Ports Assignment:** Each network segment designates a port to forward traffic, ensuring optimal paths are used.
4. **Blocking State:** Non-designated or non-root ports remain in a blocking state, preventing loops.

Benefits of RSTP

- **Improved Network Stability:** RSTP's fast convergence mechanisms reduce the risk of network outages by adapting quickly to changes in the network topology.
- **Backward Compatibility:** RSTP is fully compatible with STP, allowing a smooth transition in mixed networks where some devices still use the older protocol.

Overall, RSTP offers significant improvements over STP, making networks more resilient and responsive to changes, thereby enhancing overall reliability and performance.

Scenario: Configuring 4 Devices with RSTP

A user wants to configure 4 network devices in an RSTP topology.

Ordinarily, data will flow from SW-A directly to SW-B and SW-C. SW-D data will transit SW-C. However, if something happens that breaks links, data flow can be rerouted without administrator intervention. Follow the subsequent examples to configure each switch.

Example: Configuring RSTP on SW-A

1. Sign in to the device using administrator credentials.
 2. Go to **Redundancy > Layer 2 Redundancy > Spanning Tree**, and then click **General**.
 3. Under **STP Mode**, select **STP/RSTP** from the drop-down list.
- If this option was previously **Disabled**, numerous new features will appear.
4. Under **Compatibility**, select **RSTP**.
 5. Set **Bridge Priority** to 28672.

This must be lower than other switches on the network to establish SW-A as the root of the topology.

6. Click **Apply** to save your changes.

The list of ports becomes available.

7. Find Port **1/1** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

8. Under **Enable**, choose **Enabled** from the drop-down menu.

9. Click **Apply** to save your changes.

10. Find Port **1/3** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

11. Under **Enable**, choose **Enabled** from the drop-down menu.

12. Click **Apply** to save your changes.

13. Find Port **1/3** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

14. Under **Enable**, choose **Enabled** from the drop-down menu.

15. Click **Apply** to save your changes.

16. Find Port **1/4** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

17. Under **Enable**, choose **Enabled** from the drop-down menu.

18. Click **Apply** to save your changes.

SW-A has been configured. You can now move on to configuring SW-B.

Example: Configuring RSTP on SW-B

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Spanning Tree**, and then click **General**.
3. Under **STP Mode**, select **STP/RSTP** from the drop-down list.

If this option was previously **Disabled**, numerous new features will appear.

4. Under **Compatibility**, select **RSTP**.

5. Click **Apply** to save your changes.

The list of ports becomes available.

6. Find Port **1/1** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

7. Under **Enable**, choose **Enabled** from the drop-down menu.

8. Find Port **1/2** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

9. Under **Enable**, choose **Enabled** from the drop-down menu.

10. Click **Apply** to save your changes.

SW-B has been configured. You can now move on to configuring SW-C.

Example: Configuring RSTP on SW-C

1. Sign in to the device using administrator credentials.

2. Go to **Redundancy > Layer 2 Redundancy > Spanning Tree**, and then click **General**.

3. Under **STP Mode**, select **STP/RSTP** from the drop-down list.

If this option was previously **Disabled**, numerous new features will appear.

4. Under **Compatibility**, select **RSTP**.

5. Click **Apply** to save your changes.

The list of ports becomes available.

6. Find Port **1/1** on the list of ports, and then click the corresponding  **[Edit]**.

7. Under **Enable**, choose **Enabled** from the drop-down menu.

8. Find Port **1/2** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

9. Under **Enable**, choose **Enabled** from the drop-down menu.

10. Click **Apply** to save your changes.

SW-C has been configured. You can now move on to configuring SW-D.

Example: Configuring RSTP on SW-D

SW-D requires specific configuration to ensure that the correct paths are followed.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Spanning Tree**, and then click **General**.
3. Under **STP Mode**, select **STP/RSTP** from the drop-down list.

If this option was previously **Disabled**, numerous new features will appear.

4. Under **Compatibility**, select **RSTP**.
5. Click **Apply** to save your changes.

The list of ports becomes available.

6. Find Port **1/1** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

7. Under **Enable**, choose **Enabled** from the drop-down menu.
8. Verify that there is a value in the **Path Cost** field. If there is no value, enter a tentative value of 20,000.
9. Click **Apply** to save your changes.

10. Find Port **1/4** on the list of ports, and then click the corresponding  **[Edit]**.

The Edit Port Settings screen appears.

11. Under **Enable**, choose **Enabled** from the drop-down menu.
12. Verify that there is a value in the **Path Cost** field. If there is no value, enter a tentative value of 20,000.
13. Click **Apply** to save your changes.

14. Find Port **1/4** on the list of ports, and then click the corresponding  **[Edit]**.

15. Under **Enable**, choose **Enabled** from the drop-down menu.

16. Set **Path Cost** to 0.

17. Click **Apply** to save your changes.

With SW-D completed, all devices in the topology are complete.

Spanning Tree Settings

Menu Path: Redundancy > Layer 2 Redundancy > Spanning Tree

Spanning Tree - General

Menu Path: Redundancy > Spanning Tree - General

This page lets you configure the STP mode and its related settings.

Spanning Tree Settings - STP/RSTP

If **STP Mode** is set to **STP/RSTP**, the following settings will appear.

STP Mode *	Compatibility *	Bridge Priority *	
STP/RSTP	RSTP	32768	
		0 - 61440, Multiples of 4096	
Forward Delay Time *	Hello Time *	Max. Age *	Error Recovery Time *
15	2	20	300
4 - 30	sec. 1 - 2	sec. 6 - 40	sec. 30 - 65535
APPLY			

UI Setting	Description	Valid Range	Default Value
STP Mode	Specify the spanning tree protocol (STP) to use. <div style="background-color: #f0f0f0; padding: 5px;"> <p>Note</p> <p>MSTP and GVRP are both VLAN-related functions. When VLAN changes dynamically, MSTP needs to re-converge, which can make the system unstable due to running complex operations. When both MSTP and GVRP are used together, this can result in network instability.</p> <p>Therefore, it is recommended that network administrators avoid enabling both MSTP and GVRP.</p> </div>	Disabled / STP/RSTP/ MSTP	Disabled
Compatibility	Specify the compatibility mode to use.	STP / RSTP	RSTP
Bridge Priority	Specify the bridge priority number, which must be a multiple of 4096. Lower numbers have higher priority. A device with a higher bridge priority (e.g., a lower value) has a greater chance of being established as the root of the spanning tree topology.	Multiples of 4096 from 0 to 61440	32768
Forward Delay Time	Specify the amount of time in seconds the device waits before checking to see if it should change to a different state.	4 to 30	15
Hello Time	Specify the hello time in seconds. This is the amount of time the root waits between sending hello messages. The root of the spanning tree topology periodically sends out a "hello" message to other devices on the network to check if the topology is healthy.	1 to 2	2
Max. Age	Specify the max age in seconds. If this device is not the root, and it has not received a hello message from the root for longer than the max age time, then this device will reconfigure itself as a root. Once two or more devices on the network are recognized as a root, the devices will renegotiate a new spanning tree topology.	6 to 40	20
Error Recovery Time	Specify the error recovery time in seconds. If BPDU guard is triggered on a port, it will automatically recover to the normal state after the error recovery time.	30 to 65535	300

STP/RSTP - Port Table

If **STP Mode** is set to **STP/RSTP**, this table will appear.

Spanning Tree Settings - MSTP

If **STP Mode** is set to **MSTP**, the following settings will appear.

STP Mode *	Compatibility *		
MSTP	MSTP		
Forward Delay Time *	Hello Time *	Max. Age *	Error Recovery Time *
15	2	20	300
4 - 30 sec.	1 - 2 sec.	6 - 40 sec.	30 - 65535 sec.
Region Name	Region Revision *	Max. Hops *	
MSTP	0	20	
	4 / 32	0 - 65535	6 - 40
APPLY			

UI Setting	Description	Valid Range	Default Value
STP Mode	Specify the spanning tree protocol (STP) to use. <div style="background-color: #f0f0f0; padding: 5px;"> <p>Note</p> <p>MSTP and GVRP are both VLAN-related functions. When VLAN changes dynamically, MSTP needs to re-converge, which can make the system unstable due to running complex operations. When both MSTP and GVRP are used together, this can result in network instability.</p> <p>Therefore, it is recommended that network administrators avoid enabling both MSTP and GVRP.</p> </div>	Disabled / STP/RSTP/ MSTP	Disabled
Compatibility	Specify the compatibility mode to use.	RSTP / STP / MSTP	MSTP
Forward Delay Time	Specify the amount of time in seconds the device waits before checking to see if it should change to a different state.	4 to 30	15
Hello Time	Specify the hello time in seconds. This is the amount of time the root waits between sending hello messages. The root of the spanning tree topology periodically sends out a "hello" message to other devices on the network to check if the topology is healthy.	1 to 2	2
Max. Age	Specify the max age in seconds. If this device is not the root, and it has not received a hello message from the root for longer than the max age time, then this device will reconfigure itself as a root. Once two or more devices on the network are recognized as a root, the devices will renegotiate a new spanning tree topology.	6 to 40	20
Error Recovery Time	Specify the error recovery time in seconds. If BPDU guard is triggered on a port, it will automatically recover to the normal state after the error recovery time.	30 to 65535	300
Region Name	Specify the MSTP region name.	0 to 32 characters	MSTP

UI Setting	Description	Valid Range	Default Value
Region Revision	Specify the MSTP region revision.	0 to 65535	0
Max. Hops	Specify the maximum number of hops allowed.	6 to 40	20

BPDU Inconsistency	Shows whether BPDU is received on a port enabled by a BPDU guard.
Root Inconsistency	Shows whether the port is changed to a root port when enabled by a loop guard.
Loop Inconsistency	Shows whether a loop is detected on this port by a loop guard.

About Turbo Ring v2

Turbo Ring v2 is a high-performance, redundant network topology developed by Moxa for configuring network devices in redundant loops.

In the event of a link failure, the network can automatically reconfigure itself to maintain uninterrupted communication. Recovery times are within 20 ms for Fast Ethernet and 50 ms for Gigabit Ethernet on a network of up to 250 nodes.

Turbo Ring v2 allows connected network devices to elect a "master" switch, which blocks packets from traveling through any of the network's redundant loops and manages the network. If a section breaks, the protocol adjusts the ring so that the disconnected parts of the network establish contact. This enables continuous network operations, even when there is a fault in the network.

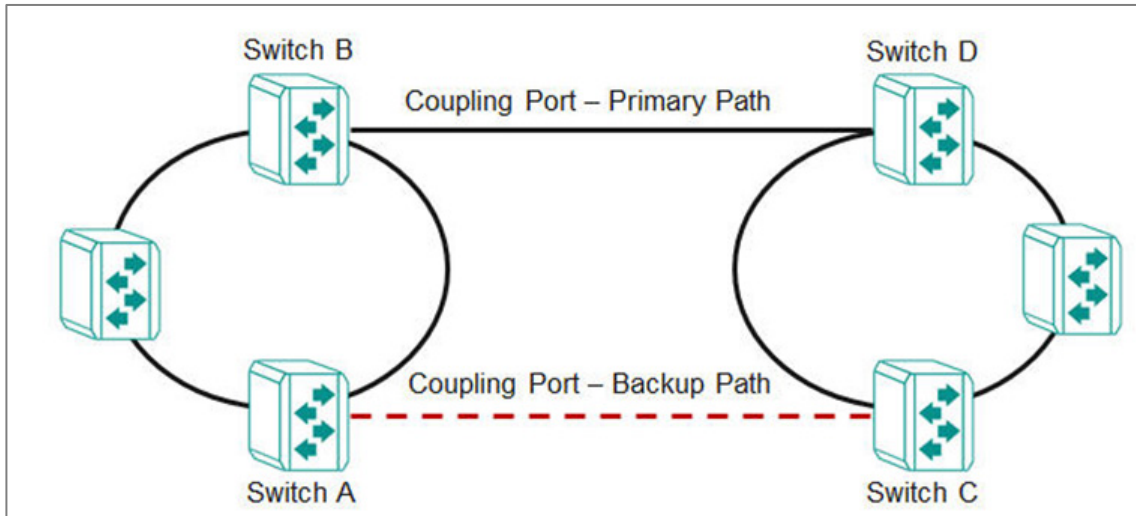

Furthermore, the election mechanism is redundant. If the "master" device itself fails, the network devices detect the failure and automatically elect another. The process occurs quickly, ensuring no interruption.

Turbo Ring v2 supports a backup segment connected to the redundant port (secondary port) on the ring "master". In this case, the backup path is easily identifiable for troubleshooting and replacement.

About Ring Coupling

Ring Coupling refers to the practice of coupling two rings together.

This may be useful when creating a large redundant ring is inconvenient or impractical, such as for devices in remote areas. Smaller redundant rings can be coupled together for inter-ring communication while still maintaining redundancy of constituent rings and couplings.

Ring coupling uses extra ports on each pair of coupled switches. In this example, that means:

- The (Primary) coupling port on Switch B monitors the main path and connects directly to the port on Switch D.
- The (Backup) coupling port on Switch A monitors the main path and connects directly to the port on Switch C.

Note

Only one coupling (primary + backup) per ring pair.

Scenario: Using Turbo Ring in a Manufacturing Plant

In this scenario, we describe a factory using a simple ring topology.

A manufacturing plant has a complex network of machines and devices that communicate with each other to keep the production line running smoothly. To ensure that the network remains stable and reliable, the plant needs to use Turbo Ring v2 to create a fault-tolerant network by forming a ring topology.

Set up Turbo Ring v2 to connect multiple networks of machines and devices to create a fault-tolerant network and achieve continuous operations.

Ensure that switches are installed and powered. Wait to connect them until the end.

To configure this scenario, do the following:

1. Configure the settings each network device for Turbo Ring v2.

See the subsequent sections for details about how to configure each device.

2. Connect the network devices in a ring topology, using ports 1 and 2 for ring segments.

If the master network device fails, the other devices in the ring will automatically detect the problem and initiate a new election process to select a new master switch, ensuring that there is no significant interruption in communication.

Example: Configuring the Master for Turbo Ring v2 in a Manufacturing Plant

Configure the device labeled SW-A for Turbo Ring v2 in our factory example.

Make sure you have NOT connected the ring ports until after you configure Turbo Ring v2 settings. Our examples use ports **1/1** and **1/2** as ring ports.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Set **Turbo Ring V2** to **Enabled**.
4. Under Ring Settings, next to **Ring 1**, click  **[Edit]**.

The Ring 1 Settings screen appears.

5. Configure all of the following:

Option	Value
Enabled	Enabled
Master	Enabled
Ring Port 1	1/1
Ring Port 2	1/2

Setting **Master** on multiple devices (or no devices) will have the following effects:

Master Setting	Result
Multiple devices set to Enabled	Ring election based on MAC addresses of Enabled devices
No devices set to Enabled	Ring election based on MAC addresses of all devices
Single device set to Enabled	Enabled device always master, failure of Enabled device results in ring election

6. Click **Apply** to save your changes.

Repeat this step on devices SW-B, SW-C, and SW-D, but with the **Master** setting set to **Disabled**. This process is outlined in the subsequent section.

Example: Configuring Non-Master Network Devices for Turbo Ring v2 in a Manufacturing Plant

Follow these steps to configure devices SW-B through SW-D in our scenario.

Make sure you have NOT connected the ring ports until after you configure Turbo Ring v2 settings. Our examples use ports **1/1** and **1/2** as ring ports.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Set **Turbo Ring V2** to **Enabled**.
4. Under Ring Settings, next to **Ring 1**, click  **[Edit]**.

The Ring 1 Settings screen appears.

5. Configure all of the following:

Option	Value
Enabled	Enabled
Master	Disabled
Ring Port 1	1/1
Ring Port 2	1/2

Setting **Master** on multiple devices (or no devices) will have the following effects:

Master Setting	Result
Multiple devices set to Enabled	Ring election based on MAC addresses of Enabled devices
No devices set to Enabled	Ring election based on MAC addresses of all devices
Single device set to Enabled	Enabled device always master, failure of Enabled device results in ring election

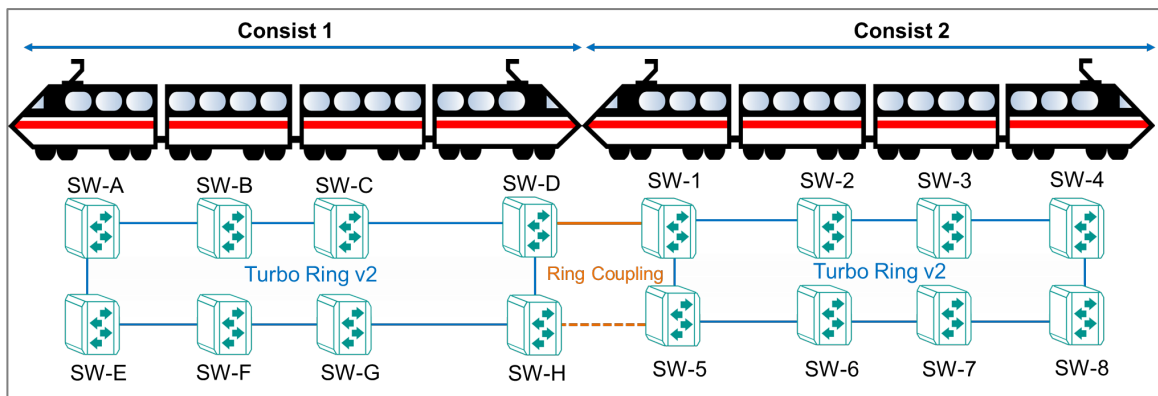

6. Click **Apply** to save your changes.

Once all devices in the ring are configured and enabled, you can connect the ring ports.

Scenario: Using Turbo Ring in an On-board Train Application

In this scenario, we describe setting up Turbo Ring v2 with ring coupling between train consists.

A railway vehicle manufacturer needs to plan a new on-board network with redundancy and flexible inter-consist communication. The customer plans a ring network with Turbo Ring v2 between multiple vehicles to form one ring per consist. Multiple consists will then use ring coupling for inter-consist communication.

This structure allows for easy administration as consists are coupled and uncoupled.

To configure this scenario, do the following:

1. Configure the settings each network device for Turbo Ring v2.
See the subsequent sections for details about how to configure each device.
2. Connect the network devices SW-A through SW-H in a ring topology, using ports 1 and 2 for segments of the ring. Do the same for SW-1 through SW-8. Do not connect the ring coupling yet.
3. Configure the Primary Coupling Path path on SW-D.
See the subsequent sections for details about how to configure ring coupling.
4. Configure the Backup Ring Coupling on SW-H.
See the subsequent sections for details about how to configure ring coupling.

Once all devices have been configured, you can connect the ring ports and coupling ports.

Example: Configuring the Master for Turbo Ring v2 in an On-board Rail Application

Make sure you have NOT connected the ring ports until after you configure Turbo Ring v2 settings. Our examples use ports **1/1** and **1/2** as ring ports.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Set **Turbo Ring V2** to **Enabled**.
4. Under Ring Settings, next to **Ring 1**, click  **[Edit]**.

The Ring 1 Settings screen appears.

5. Configure all of the following:

Option	Value
Enabled	Enabled
Master	Enabled
Ring Port 1	1/1
Ring Port 2	1/2

Setting **Master** on multiple devices (or no devices) will have the following effects:

Master Setting	Result
Multiple devices set to Enabled	Ring election based on MAC addresses of Enabled devices
No devices set to Enabled	Ring election based on MAC addresses of all devices
Single device set to Enabled	Enabled device always master, failure of Enabled device results in ring election

6. Click **Apply** to save your changes.

Once all devices in the ring are configured and enabled, you can connect the ring ports.

Continue to the next section to see how to configure ring coupling. Do not connect coupling ports until network devices have been configured.

Example: Configuring non-Master devices for Turbo Ring v2 in an On-board Rail Application

Make sure you have NOT connected the ring ports until after you configure Turbo Ring v2 settings. Our examples use ports **1/1** and **1/2** as ring ports.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Set **Turbo Ring V2** to **Enabled**.
4. Under Ring Settings, next to **Ring 1**, click  **[Edit]**.

The Ring 1 Settings screen appears.

5. Configure all of the following:

Option	Value
Enabled	Enabled
Master	Disabled
Ring Port 1	1/1
Ring Port 2	1/2

Setting **Master** on multiple devices (or no devices) will have the following effects:

Master Setting	Result
Multiple devices set to Enabled	Ring election based on MAC addresses of Enabled devices
No devices set to Enabled	Ring election based on MAC addresses of all devices
Single device set to Enabled	Enabled device always master, failure of Enabled device results in ring election

6. Click **Apply** to save your changes.

Once all devices in the ring are configured and enabled, you can connect the ring ports. Once all

Continue to the next section to see how to configure ring coupling. Do not connect coupling ports until network devices have been configured.

Example: Configuring the Primary Ring Coupling Between Consists

Both network devices that make up the ring coupling must be configured as coupling devices.

- Make sure that you have configured both rings in the scenario.
- Do not connect the coupling ports until completing setup on both devices. Our scenario assumes port **1/5** will serve as coupling port.
- Couplers should only be configured on one ring. Our example uses SW-D as the primary and SW-H as the backup. Do not configure SW-1 or SW-5 as couplers.

To configure SW-D as the primary ring coupler:

The procedure on each device is identical. To configure each device, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Under Ring Coupling Settings, click  **[Edit]**.

The Ring Coupling Settings screen appears.

4. Configure all of the following:

Option	Value
Enabled	Enabled
Coupling Mode	Coupling Primary Path
Coupling Port	1/5

5. Click **Apply** to save your changes.

The device has been configured as a primary ring coupling.

Connect the ring coupling ports. Once both devices are connected, you can move on to configuring the backup coupling.

Example: Configuring the Backup Ring Coupling Between Consists

Both network devices that make up the backup ring coupling must be configured as coupling devices.

- Make sure that you have configured both rings in the scenario.
- Do not connect the coupling ports until completing setup on both devices. Our scenario assumes port **1/5** will serve as coupling port.
- Couplers should only be configured on one ring. Our example uses SW-D as the primary and SW-H as the backup. Do not configure SW-1 or SW-5 as couplers.

To configure SW-H as the backup coupler:

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Ring V2**, and then click **Settings**.
3. Under Ring Coupling Settings, click  **[Edit]**.

The Ring Coupling Settings screen appears.

4. Configure all of the following:

Option	Value
Enabled	Enabled
Coupling Mode	Coupling Backup Path
Coupling Port	1/5

5. Click **Apply** to save your changes.

The device has been configured as a backup ring coupling.

Once the device has been configured, connect the ring coupling ports. Your coupling configuration will be complete.

Turbo Ring V2

Menu Path: Redundancy > Turbo Ring V2

This page lets you set up and configure Turbo Ring v2 redundancy for your device.

This page includes these tabs:

Coupling Port	Shows the status of the port used for ring coupling.

About Turbo Chain

Turbo Chain allows flexible expansion on top of an existing topology

This allows for flexible, cost-effective expansions. This allows you to grow existing networks without replacement the main ring while still maintaining reliability and redundancy.

Turbo Chain is a proprietary redundancy technology developed by Moxa, designed for use in widely distributed networks. It enables Ethernet switches to be connected in a daisy-chain configuration, where each switch serves as a backup path for connected devices. Turbo Chain supports system recovery times of under 20 ms for Fast Ethernet and 50 ms for Gigabit Ethernet in member port link environments.

Turbo Chain is suitable for industrial networks with complex topologies, particularly those utilizing multi-ring architectures. It allows the creation of flexible and scalable topologies with rapid media recovery.

In a typical Turbo Chain setup, each Ethernet switch is connected to two others in a daisy-chain configuration. The switches are categorized into three types: Head, Tail, and Member switches. The Head switch connects the chain to the external network, while the Tail switch provides redundancy. If the Head port is disconnected, the Tail port immediately assumes the role of data transfer, ensuring continuous communication.

This technology ensures that in the event of a link or switch failure, Turbo Chain quickly reroutes traffic to an available backup path, minimizing network downtime and maintaining uninterrupted communication.

Turbo Chain is often used in industrial automation, transportation, and surveillance applications where network reliability is critical. It is compatible with other Moxa networking technologies, such as Turbo Ring, and other Redundancy protocols like STP/RSTP, MSTP etc, to provide further redundancy and resilience for industrial networks.

To sum up, here are some of the features of Turbo Chain technology:

1. **Topology:** Turbo Chain uses a daisy-chain topology to connect Ethernet switches in a loop-free configuration.
2. **Redundancy:** Turbo Chain provides a backup path on the tail switch to ensure network availability and reduce downtime in the event of a switch or link failure.
3. **Fast failover:** Turbo Chain has a fast failover mechanism that can detect and activate backup paths in a matter of milliseconds (< 20 ms) to ensure uninterrupted communication between devices.

4. **Compatibility:** Turbo Chain is compatible with other redundancy technologies, such as Turbo Ring and RSTP, to provide even greater redundancy and resilience for industrial networks.

Example: Configuring Turbo Chain (RKS-G4000 Series)

In this example, we will configure network devices for Turbo Chain.

- Determine which devices will be the head, tail, and members of the chain. The head and tail must connect to the main LAN.
- Do not connect any of the chain devices until configuration of all devices is complete.
- Do not use any of the chain ports until configuration is completed. Do not use these ports for administration, as applying the chain configuration to these ports will disconnect you from the web GUI.

You can configure the head, tail, and member devices in any order as long as you do not connect them until after all devices are configured. Choose a device to configure and do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Turbo Chain**, and then click **Settings**.
3. Set **Turbo Chain** to **Enabled**.
4. For chain role, specify one of the following:
 - **Head** - specify only one head of the chain. This will be the primary connection to the rest of the network.
 - **Tail** - specify only one tail of the chain. This device will be the backup connection to the rest of the network.
 - **Member** - specify one or more member devices. Member devices make up the "links" between the head and the tail of the chain. Make sure that there are no loops in the chain.
5. Specify the following Ports based on the **Chain Role**:

Head Chain Role Option	Port Value
Tail Port	2/1
Member Port	2/2

Member Chain Role Option	
Member Port 1	2/1
Member Port 2	2/2

Tail Chain Role Option	
Member Port 1	2/1
Member Port 2	2/2

6. Click **Apply** to save changes.
7. Repeat this procedure to configure all devices in the chain. Once all devices have been configured, connect the devices in the chain.

Once all devices are configured and connected, packets are transmitted through the Head Port to the LAN network. If any Turbo Chain path is disconnected, the Tail Port will be activated so that packet transmission can continue.

Member Port 1	Shows the status of member port 1.
Member Port 2	Shows the status of member port 2.

About MRP (Media Redundancy Protocol)

MRP (Media Redundancy Protocol) is a network protocol based on the IEC 62439-2 that allows users to create a redundant ring system. With a recovery time of less than 200 ms, it can support up to 50 devices in each ring.

MRP includes the following roles:

MRM (Media Redundancy Manager)

MRM, also known as the Ring Manager, is a node in the network topology that manages and monitors the health of the entire ring. There is only one MRM in the network. In the event of a Link Down scenario, the MRM diagnoses the issue and notifies all MRCs (Media Redundancy Clients) to flush their MAC address table and relearn the path. Additionally, the MRM changes the port status of the primary port from blocking to forwarding to restore connectivity.

MRC (Media Redundancy Client)

MRC, also known as the Ring Client, is a node in the network topology that is monitored by the MRM (Media Redundancy Manager). However, the MRCs do not solely rely on the MRM to detect the health of the ring, they also automatically notify the MRM in the event

of a Link Down or Recovery situation. The MRC flushes its MAC address table and relearns the path when requested by the MRM.

MIM (Media Redundancy Interconnection Manager)

The function of the MIM is to observe and to control the redundant interconnection topology in order to react on interconnection faults. To cover a maximum of applications, two detection methods are provided by this international standard. The MIM can observe the interconnection topology by either:

- **LC-mode (Link check mode):** The MRP interconnection manager can observe the interconnection topology by reacting directly on interconnection port link change notification messages
- **RC-mode (Ring check mode):** The MRP interconnection manager can observe the interconnection topology by sending test frames on the interconnection port over the connected rings and receiving them over its ring ports, checking in both directions

MIC (Media Redundancy Interconnection Client)

The other three nodes in the interconnection topology have the role of media redundancy interconnection clients (MIC), in addition to the role of a MRC or MRM. The MIC reacts on received reconfiguration frames from the MIM, it can detect and signal link changes of its interconnection port, and it can issue link change notification messages.

Configuring Ring Managers and Clients

MRP Managers and Clients must be configured before the rings can be used.

- Determine which devices will be the Manager and the Clients. There can only be a single manager.
- Do not connect any of the devices until configuration of all devices is complete.
- Do not use any of the ring ports until configuration is completed. Do not use these ports for administration, as applying the chain configuration to these ports will disconnect you from the web GUI.

Choose a device to configure and do the following:

1. Sign in to the device using administrator credentials.

2. Go to **Redundancy > Layer 2 Redundancy > MRP**, and then click **Settings**.
3. Under Media Redundancy Protocol, choose **Enabled** from the drop-down menu.
4. Specify the following based on the **Role**:

Ring Manager Option	Ring Manager Value
Role	Ring Manager
VLAN ID	Specify the VLAN ID for the ring
Domain UUID	Choose either Default or PROFITNET (Siemens) according to your network configuration
React on Link Change	It is recommended to set this to Enabled . This setting allows the Ring Manager to quickly respond to topology changes, both when a link goes down and when the original topology is restored.
Ring Port 1	Specify the first redundant ring port
Ring Port 2	Specify the second redundant ring port

Ring Client Option	Ring Client Value
Role	Ring Client
VLAN ID	Specify the VLAN ID for the ring
Domain UUID	Choose either Default or PROFITNET (Siemens) according to your network configuration
Ring Port 1	Specify the first redundant ring port
Ring Port 2	Specify the second redundant ring port

5. Click **Apply** to save your changes.

Once all devices are configured, you can connect the ring ports.

About Multiple Dual Homing

Multiple Dual Homing is a layer 2 function that connects two network topologies using a single Ethernet switch, enabling redundancy protocols on each topology. It links either two devices or two rings to two independent connection points, activating a secondary

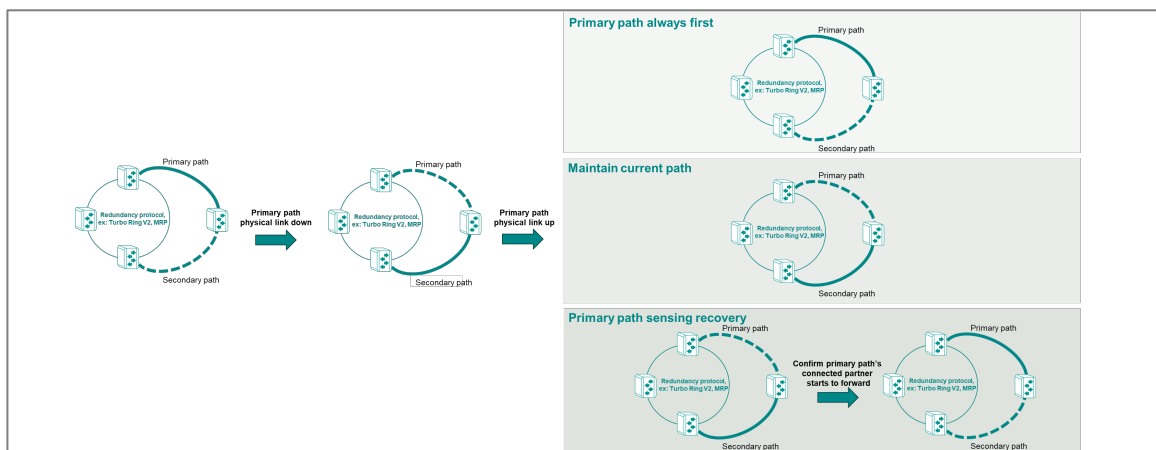

path if the primary path fails. Multiple Dual Homing allows for several dual-homing sessions simultaneously, supporting multiple redundant connections.

Multiple Dual Homing In Depth

To configure Multiple Dual Homing, you must specify the primary port and secondary (fallback) port for the switch, which correspond to the primary and secondary paths respectively. The primary path serves as the default forwarding path, with the secondary path blocked until the primary goes down.

Multiple dual homing supports three path switching modes:

- **Primary path always first** (default). Automatically switches back to the primary path when it recovers, blocking the secondary path regardless of its status. Recovery time depends on the connected partner's data and physical link timing.
- **Maintain current path.** Maintains the current (secondary) path even if the primary path recovers, until the secondary path disconnects. Reduces the cost of frequent switching.
- **Primary path sensing recovery.** Switches to the primary path once the primary port confirms that the partner device is forwarding, immediately blocking the secondary port. This mode minimizes recovery time.

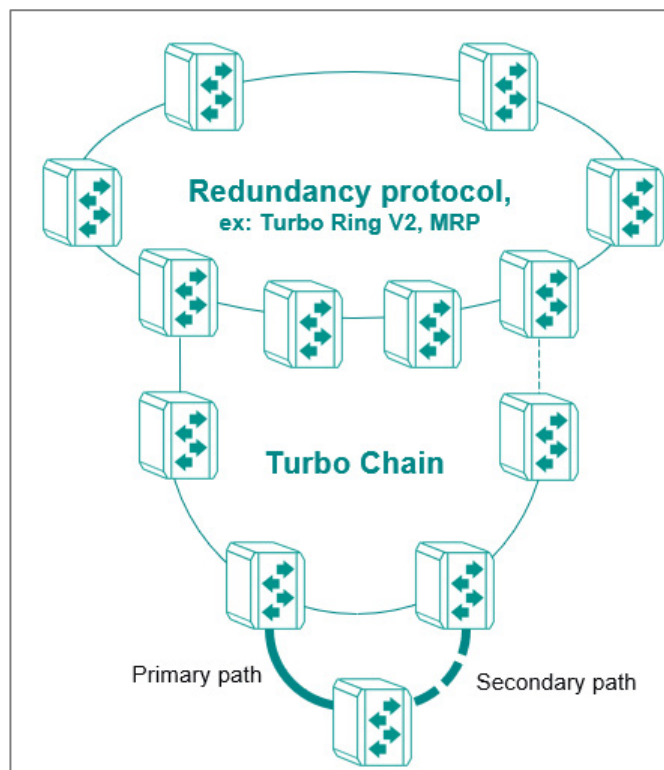

Note

It is highly recommended to configure Linkup Delay to avoid rapid oscillation between primary and secondary paths.

When used in conjunction with other Moxa redundancy protocols, such as Turbo Ring v2 and Turbo Chain, Multiple Dual Homing can significantly reduce fault recovery costs.

	Fast Ethernet	Gigabit Copper	SFP
Turbo Ring/Turbo Chain	20 ms	800 ms	50 ms

Multiple Dual Homing can coexist with other redundancy protocols provided these protocols are configured on different ports. Dual Homing and other redundancy protocols are mutually exclusive on any logical port, including trunking ports.

Note

Port-Channel ports can be used with Dual-homing, but have the following limitations:

1. Port-Channel and member ports can not be deleted while set as a Primary or Secondary port.
2. Ports assigned as a Primary or Secondary port cannot be assigned to Port-Channel member ports while Multiple Dual Homing is enabled.

Note

Ports with IEEE 802.1X or MAB enabled cannot be specified as Primary or Secondary ports due to the possibility of interruption. Port authorization and redundancy serve different purposes, and should remain on separate ports.

Configuring Multiple Dual Homing

Do not connect homing ports until setup is complete, otherwise you may risk network looping.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Multiple Dual Homing**, and then choose **Settings**.
3. Under **Settings**, click **Multiple Dual Homing** and choose **Enabled** from the drop-down list.
4. Specify a **Path Switching Mode**:

Option	Description
Primary path always first	Reconnects as soon as physical media is available, with recovery time determined by data link responsiveness.
Maintain current path	After switching paths, device will not switch back unless the secondary becomes unavailable, minimizing recovery time.
Primary path sensing recovery	Reconnects when primary path data link goes back up, reducing recovery time.

5. Click **Apply** to save your changes.

- To edit a Session, under Dual Homing Table Settings, click  **[Edit]** next to the corresponding **Session ID**.

The Edit Session Settings screen appears.

- Specify all of the following, and click **Apply** to save your changes:

Option	Value
Status	Enabled
Primary Port	Specify the Port used as the primary path. This port will be the default link to the network.
Secondary Port	Specify the Port used as the secondary path. This port will be the backup link to the network.

The corresponding **Session ID** updates.

- Repeat this step to configure additional sessions.

Multiple Dual Homing has been configured. You can now connect ports.

It is highly recommended to configure **Linkup Delay** to avoid rapid oscillation between primary and secondary paths.

Configuring Linkup Delay

Linkup Delay adds a brief pause before establishing a link, which can be useful to avoid oscillation or "flapping" in complex network setups.

- Sign in to the device with administrator credentials.
- Go to **Port > Port Interface > Linkup Delay**.
- Under **Linkup Delay**, select **Enable** from the drop down list, and then click **Apply**.
- Configure Linkup Delay on each port by clicking  **[Edit]** next to the corresponding **Port**, configuring the following, and then clicking **Apply**:

Linkup Delay	Enabled
---------------------	----------------

Delay Time	2 seconds is the default and recommended setting.
Copy configurations to ports	Optionally, duplicate configuration on other ports. For users configuring Multiple Dual Homing, we recommend configuring both primary and backup ports with Linkup Delay.

Linkup Delay settings will be shown in the table.

Secondary Port Status	Shows the current status of the secondary port for the session.

About Multiple Network Coupling

Multiple Network Coupling is a proprietary Moxa feature designed to address various scenarios where heterogeneous redundant networks need to be connected to operate together.

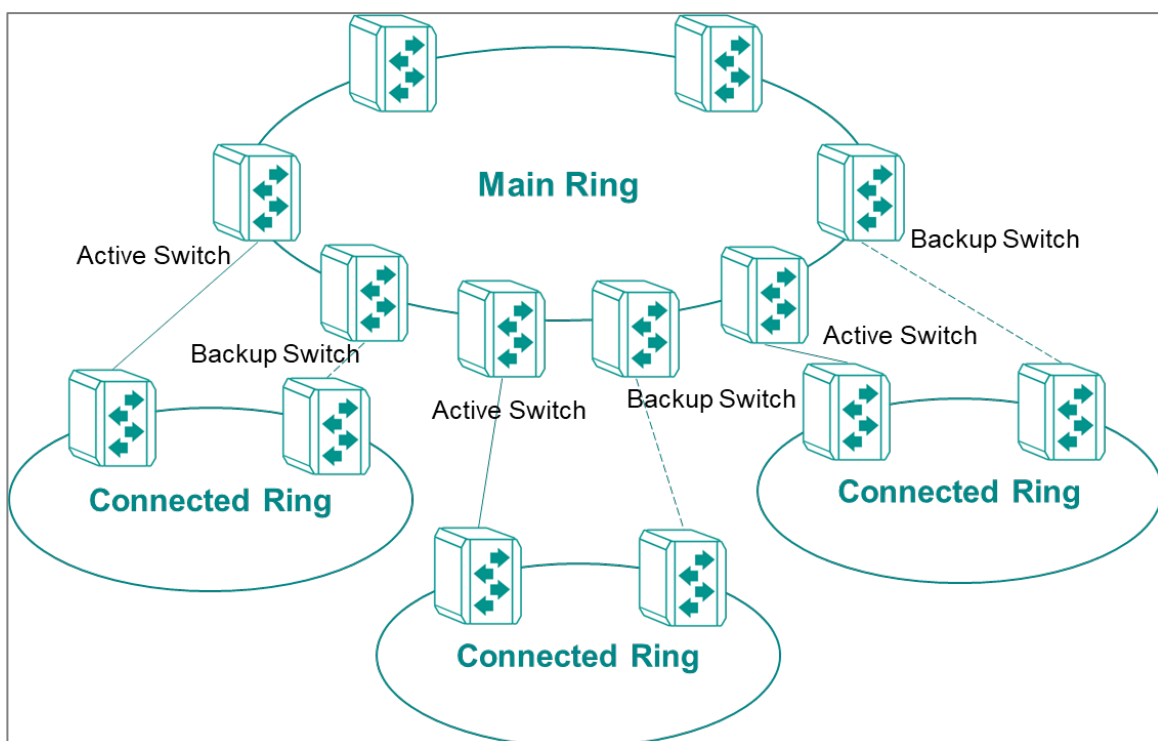

By connecting different redundant protocols, this feature not only provides flexibility for topologies applied in different applications, but also raises the level of overall network

availability and stability by making sure the path between different redundant protocols is always unimpeded without looping.

Multiple Network Coupling includes a Main Ring and Connected Rings, and these rings can operate using the same or different redundancy protocols. This feature uses two switches to couple the two rings, and switches in the Main Ring control the coupling links to make sure communication between the two rings is smooth.

Multiple Network Coupling In Depth

The structure of Multiple Network Coupling includes a Main Ring and Connected Rings.

MX-NOS supports the following redundancy protocols for the Main Ring:

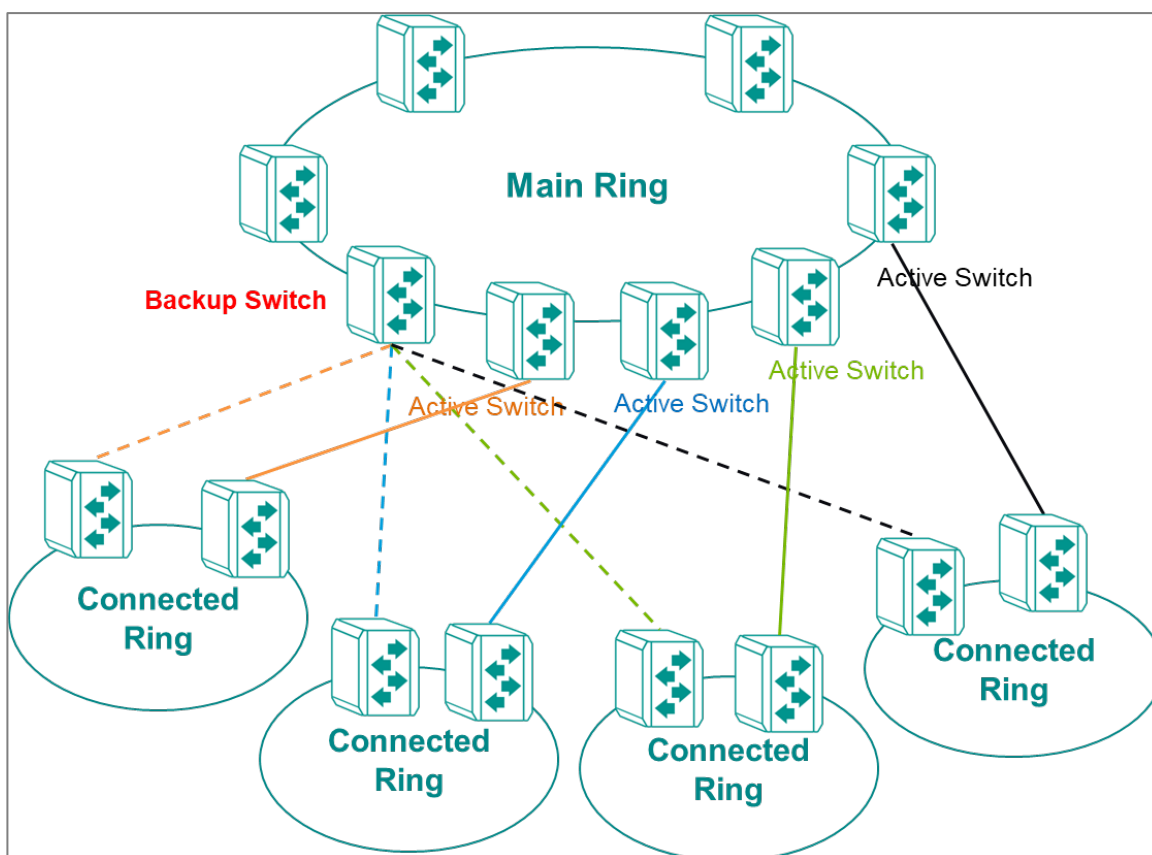

- Turbo Ring v2
- MRP
- HSR

MX-NOS supports the following redundancy protocols for Connected Rings:

- Turbo Ring v2
- MRP

- RSTP

The redundancy protocol on the Main Ring is coupled with the redundancy protocols running on the Connected Rings. Switches in the Main Ring used to couple the Connected Rings are designated as Active Switches or Backup Switches. Active Switches are responsible for the primary path and Backup Switches are responsible for the backup path. The communication protocols designed for the Active Switch and Backup Switch ensure traffic moves smoothly between the rings without looping. The Backup path will take over when the Primary path link is down, and vice versa.

Multiple Network Coupling Limitations

- The Main Ring can couple with up to 16 Connected Rings.
- A switch in the Main Ring can support up to 4 paths to Connected Rings.
- A Backup Switch can pair with up to 4 Active Switches.
- An Active Switch can only have one Backup Switch.

About Topologies for Multiple Network Coupling

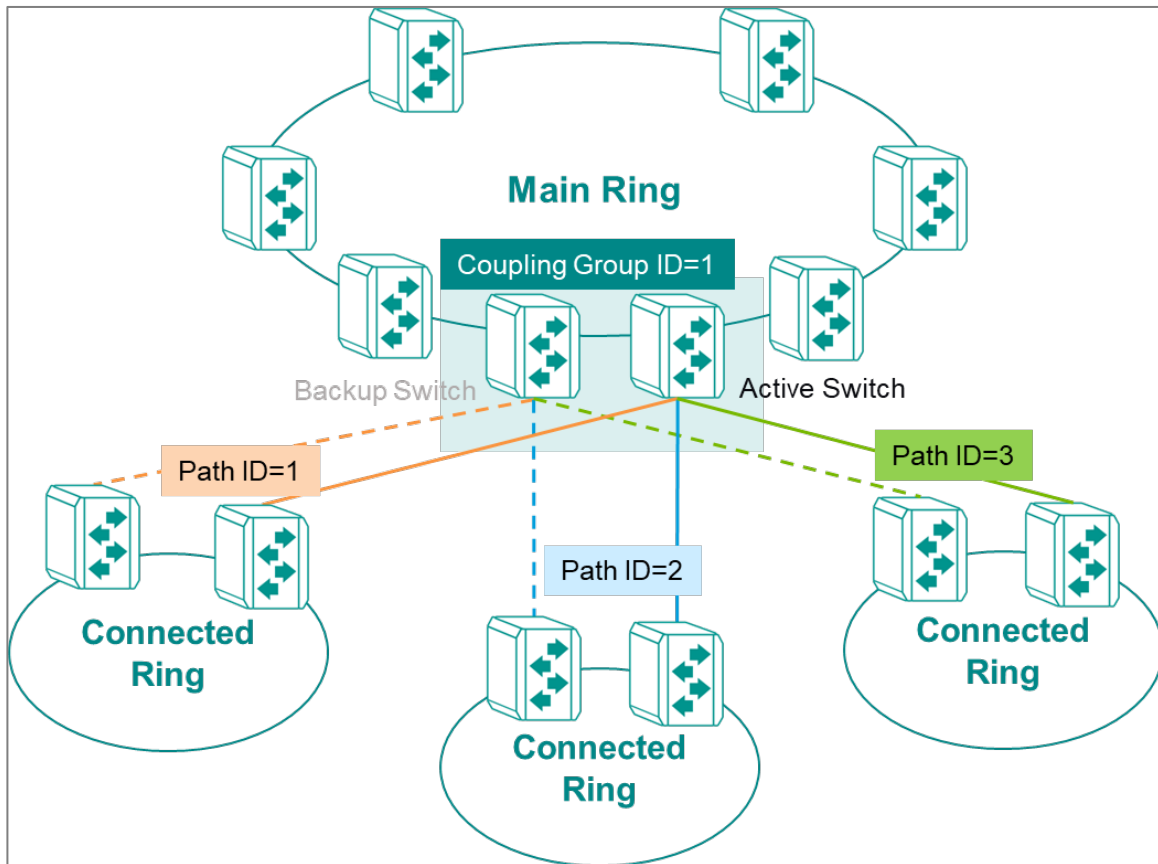

These are some examples of different Multiple Network Coupling deployments and guidelines for topology planning.

Guidelines for Topologies

- Coupling Groups refer to switches on the Main Ring, and the Connected Ring switches attached to them.
 - Each Coupling Group can only have one backup switch.
- Path IDs uniquely identify Connected Rings within the same coupling group.
 - Multiple Connected Rings connected to the same Coupling Group require separate Path IDs.

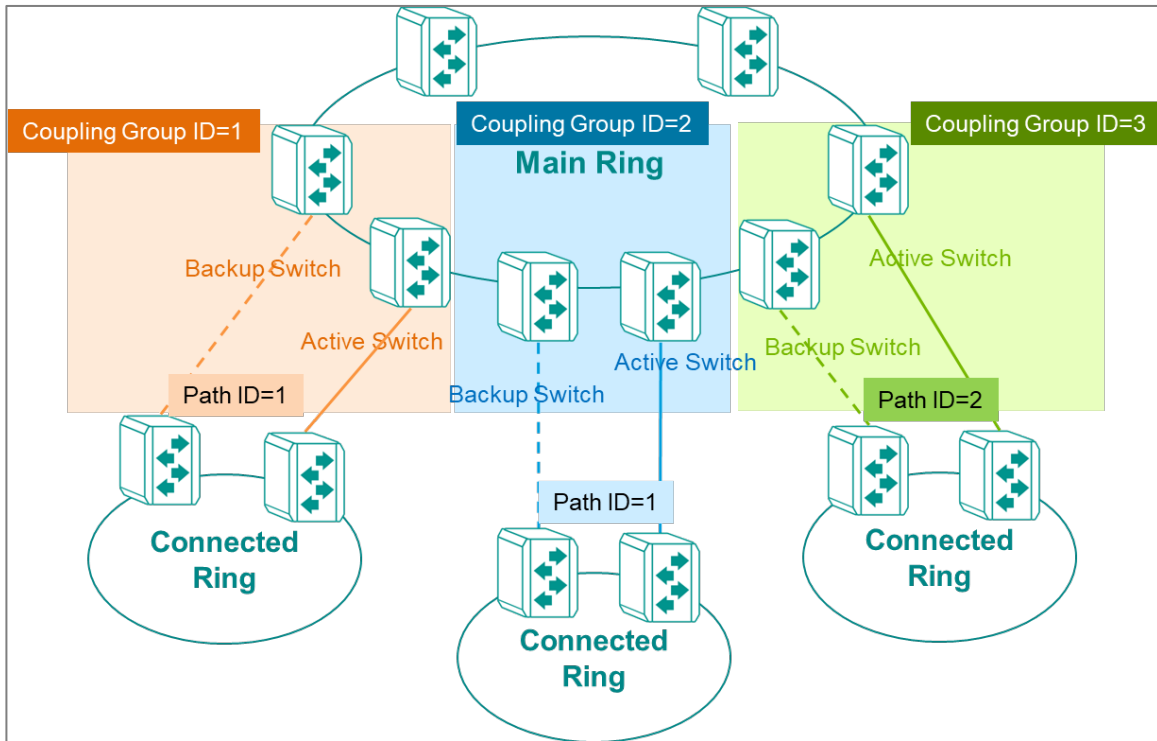

One Coupling Group, Shared Active and Backup Switches

This topology shares the same Main Ring switches for all Connected Rings. This is a simple, centralized configuration.

Three Coupling Groups, Separate Active and Backup Switches

This topology uses separate pairs of Main Ring switches for each Connected Ring, providing maximum redundancy.

One Coupling Group, Separate Active Switches, Shared Backup Switch

In this hybrid topology, connected rings share a single Backup Switch while maintaining separate Active Switches.

Configuring Multiple Network Coupling

Multiple Network Coupling generally only needs configuration on Main Ring switches.

- Do not connect Main Ring switches and Connected Ring switches until Multiple Network Coupling is configured.
- Make sure that compatible redundancy protocols have been configured on each ring. As of November 2024, Multiple Network Coupling supports Turbo Ring v2, MRP, and RSTP.

Configure Multiple Network coupling on each "Main Ring" device.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Layer 2 Redundancy > Multiple Network Coupling**, and then click **Settings**.
3. Configure all of the following, and then click **Apply**:

Option	Value
Multiple Network Coupling	Enabled

Option	Value
Coupling switch role	<ul style="list-style-type: none"> • Active: device will serve as the active switch • Backup: device will serve as the backup switch <p>Only one backup switch supported per connected ring.</p>
Coupling group ID	Specify the coupling group ID from the dropdown list.
Coupling polling interval	<ul style="list-style-type: none"> • 80 ms: recommended for up to 16 path IDs. • 40 ms: recommended for up to 8 path IDs.

- To configure Path IDs (corresponding to each Connected Ring), under Coupling Table Settings, click the corresponding  **[Edit]**. The Edit Path ID Settings screen appears.
- Configure all of the following, and then click **Apply**:

Option	Value
Status	Enabled
Path ID	Specify the Path ID, corresponding to your Connected Ring
Coupling Port	Specify the port to which your Connected Ring will be connected.

- Repeat this step to configure additional Path IDs and corresponding Connected Rings.

Repeat this procedure for each switch in each coupling group.

For Connected Rings with non-Moxa switches that have RSTP enabled, make sure to enable edge ports on each port connected to the Main Ring.

Multiple Network Coupling

Multiple Network Coupling - Settings

Menu Path: Redundancy > Layer 2 Redundancy > Multiple Network Coupling - Settings

This page lets you enable and configure Multiple Network Coupling for your device.

Multiple Network Coupling Settings

The screenshot shows the configuration interface for Multiple Network Coupling. It includes the following settings:

- Multiple Network Coupling**: Enabled
- Main Ring Protocol**: Turbo Ring V2
- Coupling switch role**: Backup
- Coupling group ID**: 3
- Coupling polling interval**: 80 ms

An **APPLY** button is located at the bottom left of the settings area.

UI Setting	Description	Valid Range	Default Value
Multiple Network Coupling	Enable or disable Multiple Network Coupling for your device. This should be enabled if you want the device act as an active switch or backup switch.	Enabled / Disabled	Disabled
Main Ring Protocol	Shows the redundant protocol being used for the Main Ring. This value cannot be changed here.	N/A	N/A

Note

The redundant protocol you want to enable in the Main Ring must be enabled before enabling Multiple Network Coupling.

The redundant protocols supported in the Main Ring include:

- Turbo Ring V2
- MRP
- HSR

UI Setting	Description	Valid Range	Default Value
Coupling switch role	<p>Specify the device's switch role in the Main Ring.</p> <ul style="list-style-type: none"> Active: The device will act as the active switch responsible for the primary path. Backup: The device will act as the backup switch responsible for the backup path to the Connected Ring. 	Active / Backup	Active
Coupling group ID	<p>Specify the coupling group ID for the switch.</p> <div style="background-color: #f0f0f0; padding: 5px;"> <p> Note</p> <p>The coupling group ID for the paired active switch and backup switch must be the same.</p> </div>	1 to 16	1
Coupling polling interval	<p>Specify the coupling polling interval in milliseconds used to check if the coupling path is forwarding.</p> <div style="background-color: #f0f0f0; padding: 5px;"> <p> Note</p> <p>The maximum number of active/backup switch pairs is 16. We suggest setting the Coupling polling interval to 80 ms if your topology has 16 pairs of active/backup switches to Connected Rings, and 40 ms if you have 8 pairs of active/backup switches.</p> </div>	40, 80	80

About IEC 62439-3

IEC 62439-3 is an international standard defining protocols to achieve seamless, high-availability Ethernet networks for industrial automation and mission-critical applications.

It specifies two key redundancy protocols:

- **Parallel Redundancy Protocol (PRP):** Enables devices to connect simultaneously to two independent LANs. Each frame is transmitted over both LANs in parallel, ensuring zero recovery time in case of a single network failure.
- **High-availability Seamless Redundancy (HSR):** Uses a ring topology where each device forwards frames along the ring, sending duplicates in both directions. This also provides seamless failover without frame loss.

These protocols allow systems to tolerate failures in any single network without interrupting communication. PRP and HSR support deterministic redundancy, ensuring continuous data transmission without switchover delays, which is essential for real-time control systems, substation automation, and other applications requiring uninterrupted operation.

About RedBoxes

A Redundancy Box (RedBox) is a specialized network device defined in IEC 62439-3 for connecting nodes that do not natively support HSR or PRP, or for coupling PRP and HSR

networks together. It allows standard Ethernet devices or different redundancy domains to communicate seamlessly within a high-availability network.

Key functions of a RedBox

- **Connects non-redundant devices:** RedBox lets standard single-port Ethernet devices join a redundant HSR ring or PRP network, providing them with seamless redundancy without modifying the end device itself.
- **Couples PRP and HSR domains:** RedBox can act as a bridge between a PRP dual-LAN network and an HSR ring, enabling traffic to flow between them while maintaining redundancy behavior and supervision mechanisms.

Primary roles of RedBoxes:

- **SAN-to-HSR:** Connects Singly Attached Nodes (SANs) to an HSR ring.
- **SAN-to-PRP:** Connects a SAN to both PRP LAN A and LAN B.
- **PRP-to-HSR:** Acts as a **coupling bridge** between a PRP domain and an HSR ring.

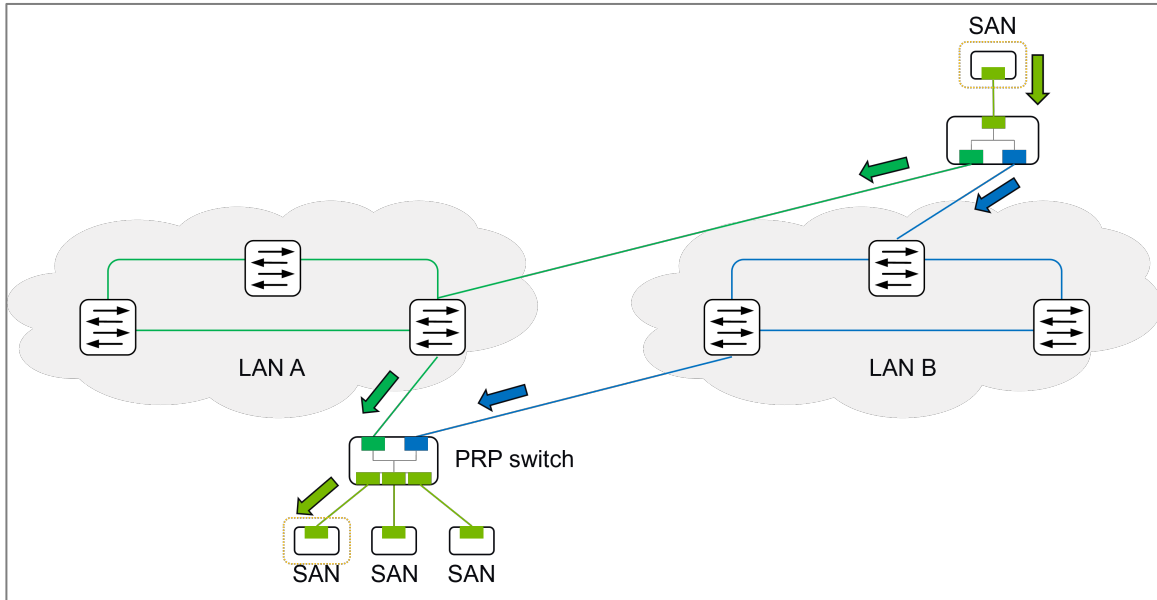

PRP in Depth

PRP allows a redundant connection across two independent LANs simultaneously. Because each frame is duplicated, there is no transition time in the event of a failure. PRP can be useful when you need redundancy with existing networks. As long as both PRP devices support the PRP protocol, Intermediate networks do not need to be PRP aware, and need only provide Layer 2 paths between PRP devices.

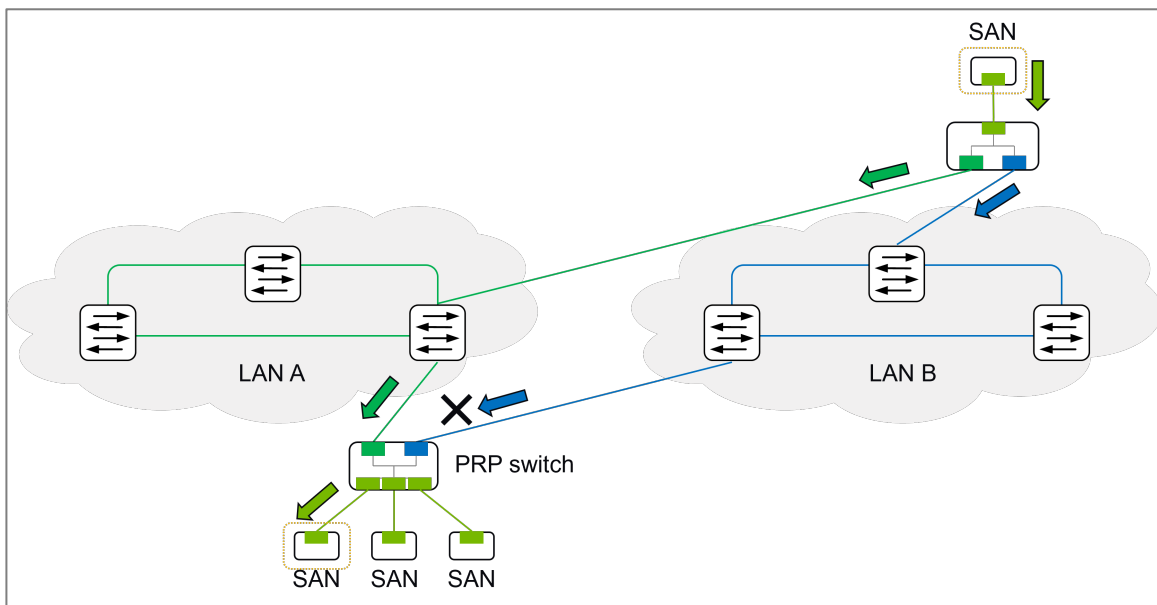

PRP devices use dedicated ports. Those ports should have the same MAC and IP address (unique within their respective networks, but duplicated on both ports A and B).

PRP network devices often host multiple Singly Attached Nodes (SANs)—conventional network devices that do not support PRP redundancy, such as end-user devices or industrial equipment with single network interfaces.

Because PRP connections use specialized devices with unique identifiers, risk of looping is minimized.

In this example, a PRP Switch connects to a RedBox by traversing two different ring networks, LAN A (Green) and LAN B (Blue). Note that LAN B does not connect through the same device; this is by design. The PRP link over LAN B will transparently benefit from redundancy protocols ordinarily operating over LAN B, without requiring additional configuration. Although this example employs ring topologies in LAN A and B, most topologies with clear L2 paths are supported.

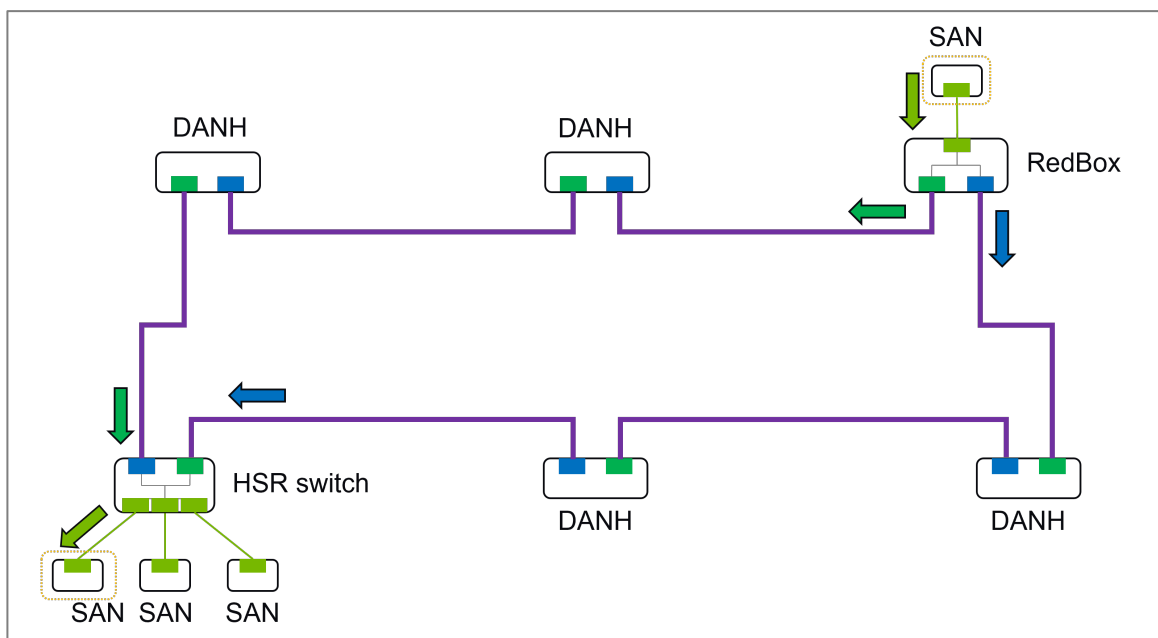

In the event of a block on LAN B, LAN A continues transmitting packets as normal—with zero transition time. The connection is automatically restored when the block is resolved.

HSR in Depth

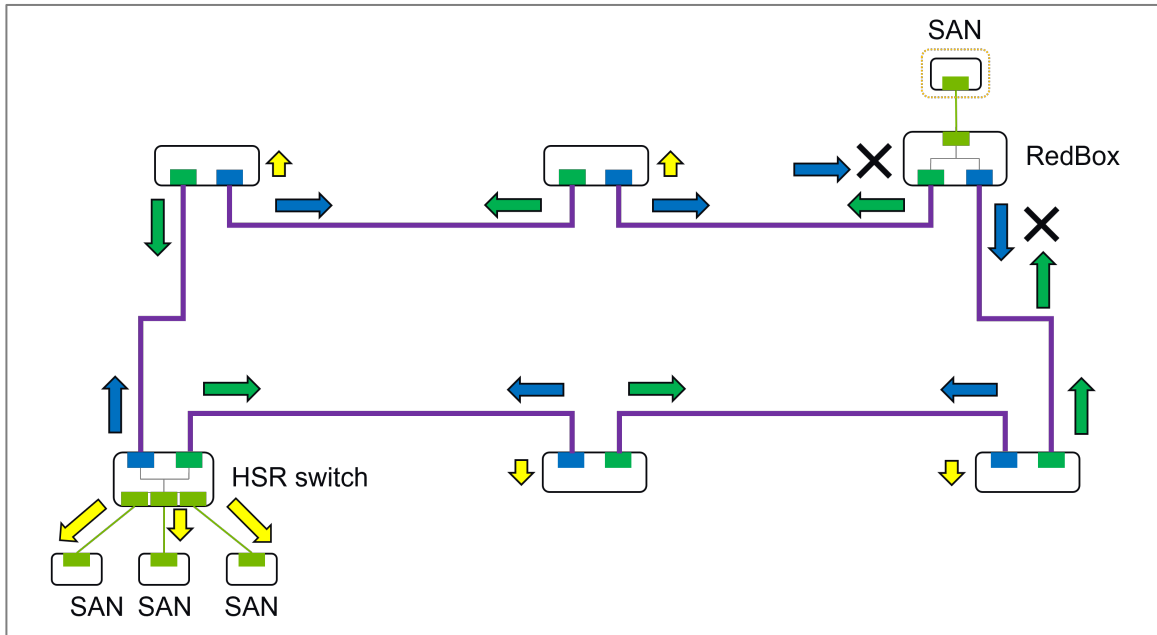

High-availability Seamless Redundancy (HSR) is a redundant ring topology. HSR duplicates frames along both paths of the ring to ensure zero transition time in the event of a failure.

Like PRP, HSR uses dedicated ports (Port A/ Port B) on each network device to form the ring.

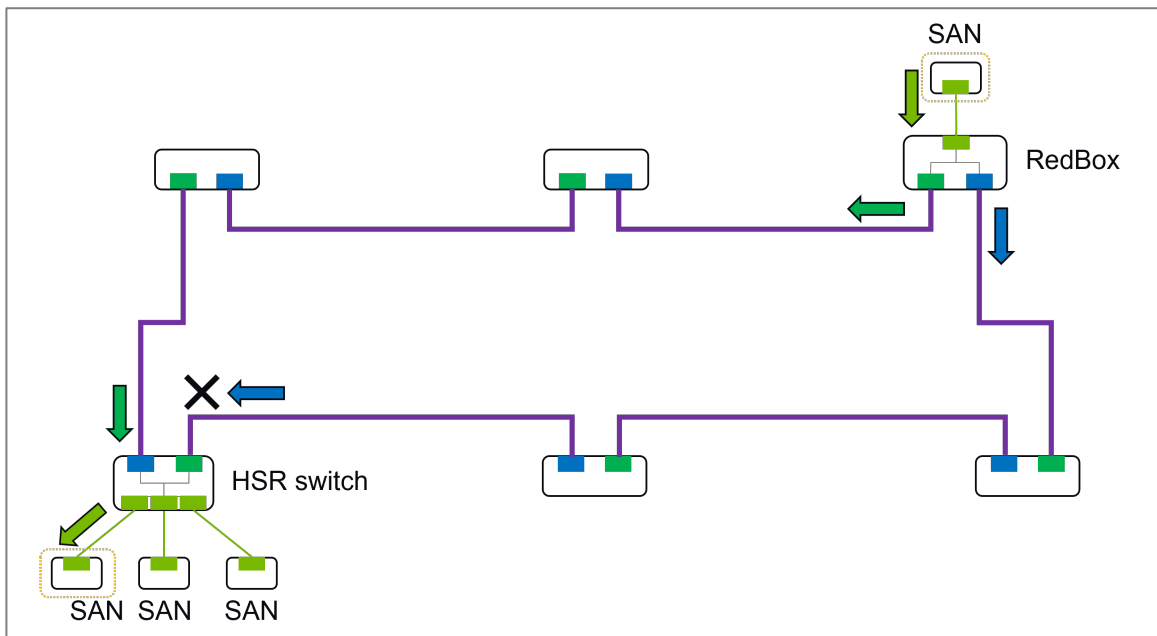

HSR network devices often host multiple Singly Attached Nodes (SANs)—conventional network devices that do not support HSR redundancy, such as end-user devices or industrial equipment with single network interfaces.

An HSR switch connects to the ring by connecting to dedicated HSR ports (Port A/B). Frames are duplicated and sent through both directions of the ring. Frames sent from the RedBox to the HSR switch traverse the network in both directions, with each device retransmitting frames until they arrive. The HSR switch recognizes the frames have converged on their destination, and does not transmit them further. The frames are then passed to destination SANs.

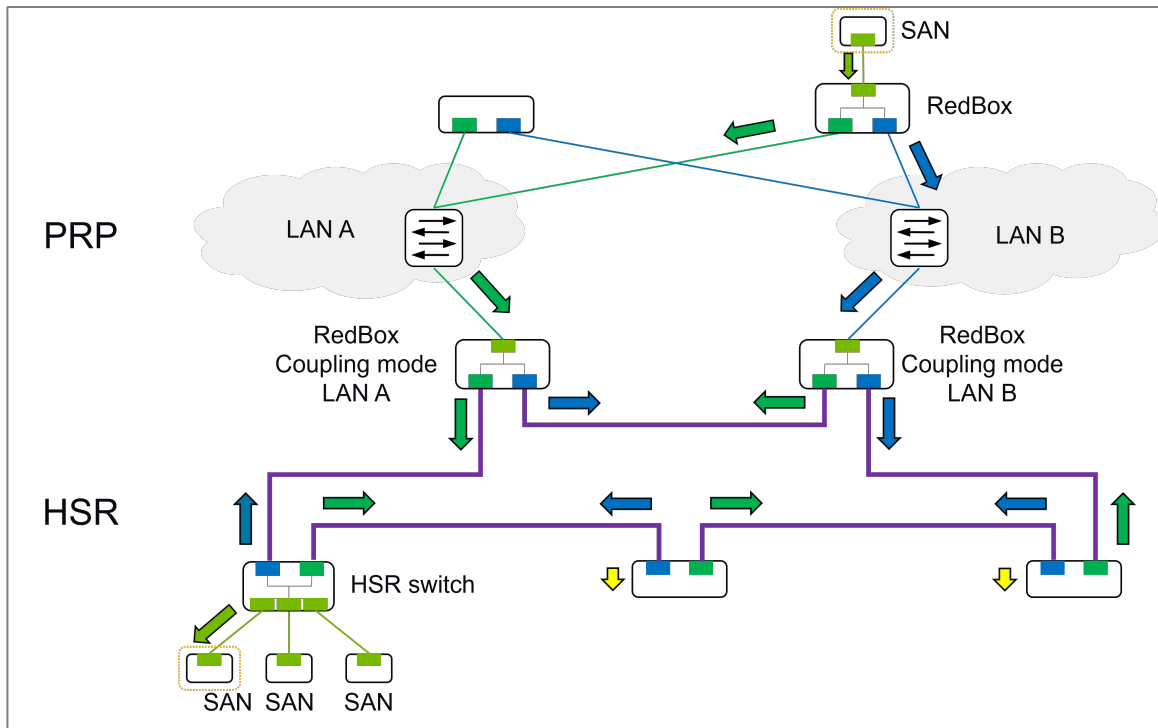

Broadcast frames are relayed to the entire ring. Frames are not re-forwarded by their originator to avoid looping.

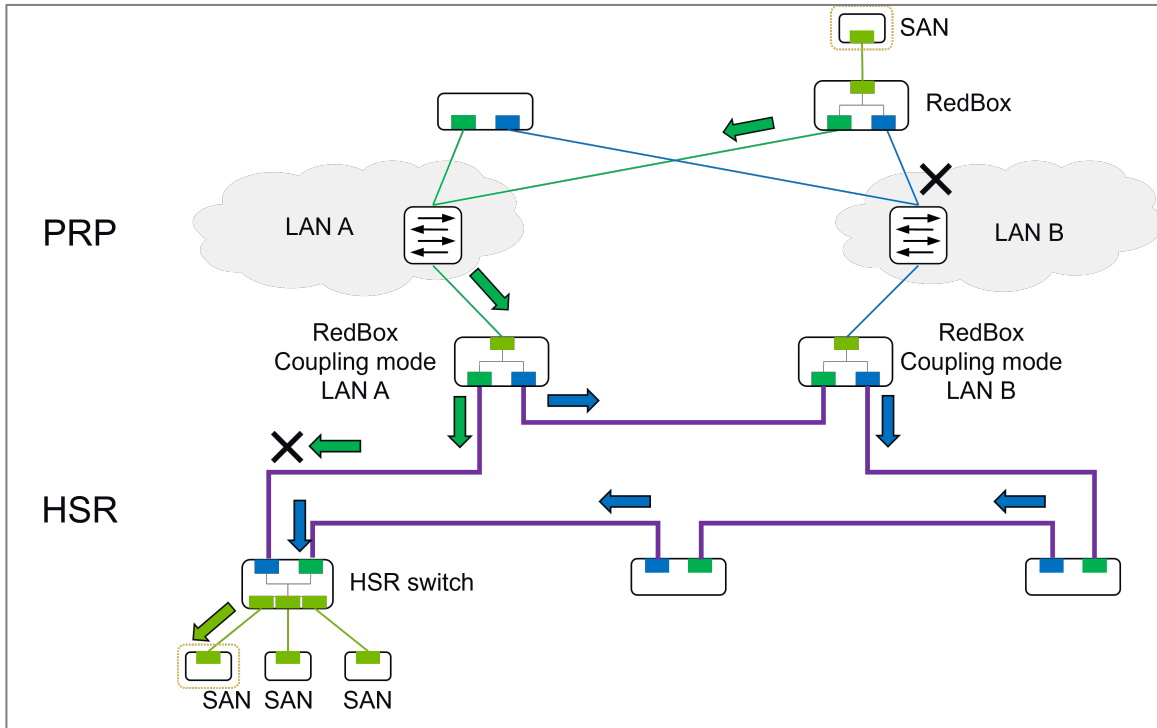

In the event of a failure in one segment of the ring, packets continue to flow over the active segment. Unicast frames are forwarded across the ring until they reach their intended destination.

About PRP-HSR Single Coupling

Different kinds of networks can be coupled together to leverage maximum redundancy without replacing existing equipment.

In this example, an HSR ring is bridged over two different, non-HSR-aware and non-PRP-aware LANs. Frames from the RedBox SAN first traverse the PRP network, then through the HSR couplings, and are then relayed along the ring until they reach the destination HSR switch.

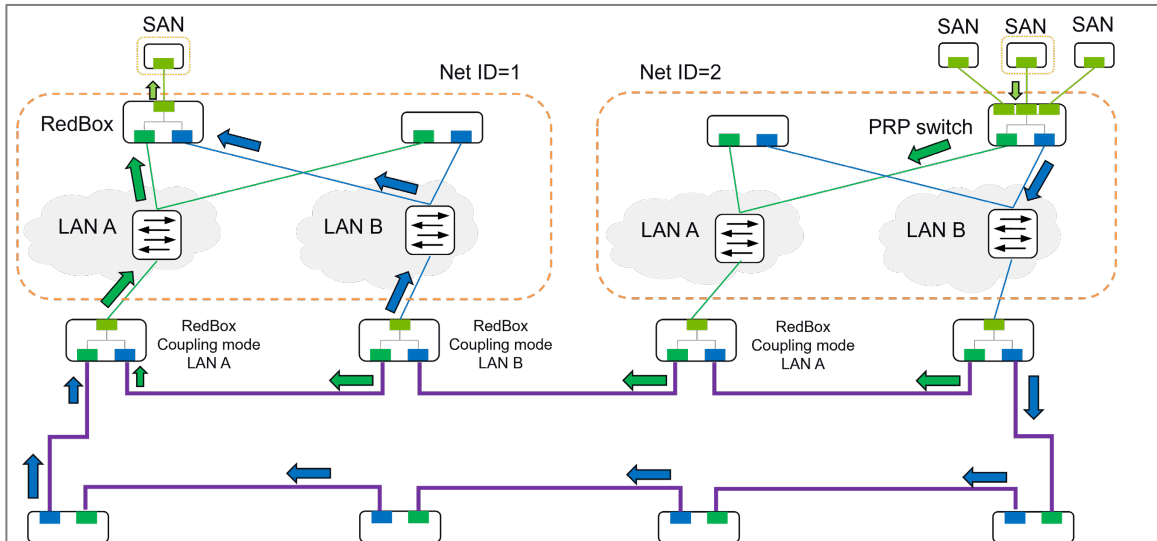

In the event of one or more failures, frames are routed along available routes and networks until they reach their destination without failover time.

Note

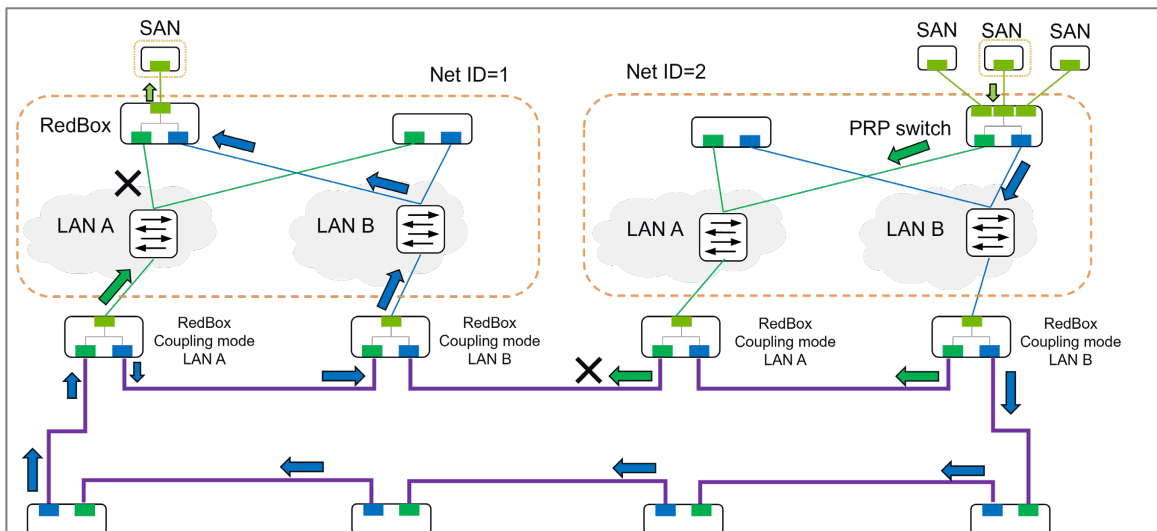

Important: Coupling mode must be enabled on links between PRP and HSR to avoid looping of the PRP (LAN A/B) networks.

About PRP-HSR Multiple Coupling

HSR and PRP can be further combined to link multiple networks with high resiliency and zero failover time.

In this example, two PRP networks are connected by an HSR ring. Outbound frames from the SAN on the PRP Network ID 2 are duplicated across the PRP network, and passed to the HSR network where they are passed over the HSR ring until reaching the PRP Network ID 1, where they are duplicated across the PRP network before converging on the destination RedBox, which forwards them to the SAN.

In the event of multiple failures in the network (in this case, a gap in the ring and a gap in the PRP network), frames continue to be sent over the remaining redundant links. Because no rerouting is required, there is no failover time, despite network complexity.

Note

Important: Coupling mode must be enabled on links between PRP and HSR to avoid looping of the PRP (LAN A/B) networks.

Note

Important: Because there are multiple PRP networks, it is vital that all PRP-aware devices on each net be configured with the correct Net IDs to avoid looping.

Considerations for PRP/HSR Network Planning

Here are some design tips when planning a PRP and HSR deployment.

For PRP and HSR networks:

- Configure Supervision Frame on all PRP/HSR devices. They are a mandatory part of IEC 62439-3, and the networks will not function correctly without configuration.
- Avoid single points of failure. Leverage redundancy in each part of the network, including redundant power supplies, and network redundancy in any intermediate networks.
- PRP/HSR are interoperable, but other redundancy protocols such as Turbo Chain, Turbo Ring, and MRP cannot be enabled on the same ports at the same time.
- Port mirroring and SPAN are supported (1-to-1 or N-to-1) with the following caveats:
 - Ports A and B cannot be set as mirror destination ports.
 - Ports A and B cannot be set as RSPAN source ports.
- Supports QoS, DHCP Relay Agent, and Access Control Lists.

For PRP networks:

- Use similar topologies in both networks to keep latencies similar.
- Limit SANs to a single network.
- Do not connect non-PRP devices to both intermediate LANs to avoid looping. Only PRP-aware devices should be used.

- Do not connect RedBoxes with Layer 2 paths that use bridges to PRP intermediate networks.
- Make sure that LAN A and B are fully separated.

For HSR Networks:

- Ensure that all devices directly on the HSR ring are HSR aware.

About Supervision Frames

Supervision frames are specialized Ethernet frames defined by IEC 62439-3 to monitor network health in PRP and HSR systems. Each node periodically sends supervision frames to announce its presence and unique identifier to other nodes. Devices maintain a table of known nodes based on received supervision frames.

The supervision mechanism serves multiple purposes:

- **Presence detection:** Verifies that nodes are online and reachable.
- **Failure detection:** Absence of supervision frames beyond a configured time threshold indicates possible node or network failure.

Supervision frames use reserved multicast destination addresses, enabling all PRP/HSR-capable devices to receive them without broadcasting to every device on the network.

Enabling PRP/HSR

PRP/HSR must be enabled to function.

- Ensure that Turbo Chain, Turbo Ring, and MRP are disabled on this device.
1. Sign in to the device with administrator credentials.
 2. Go to **Redundancy > IEC 62439 > PRP/HSR**.
 3. Configure the following:

Option	Value
PRP/HSR Protocol	Choose <ul style="list-style-type: none"> • PRP for devices in a PRP network. • HSR for devices in an HSR ring. • Coupling for devices that are coupled between HSR rings and PRP networks.

Option	Value
Entry Forget Time	Choose: <ul style="list-style-type: none"> • 100 ms for Fast Ethernet • 10 ms for Gigabit Ethernet Since PRP and HSR use duplicate frames in loop-like topologies, frames are briefly stored in a duplicate table to make sure the device does not forward a frame more than once. This value specifies how long those entries are maintained.
Net ID	For PRP/HSR Protocol: Coupling , choose a Net ID from 1 to 7 , which corresponds to the PRP network to which the device attaches.
LAN ID	For PRP/HSR Protocol: Coupling , choose LAN A or LAN B which corresponds to the PRP network to which the device attaches.

4. Select **Apply** to save your changes.

Configuring Supervision Frames

Supervision Frames must be configured for PRP/HSR to function.

1. Sign in to the device using administrator credentials.
2. Go to **Redundancy > IEC 62439 > Supervision Frame**, and then selecting **General**.
3. Configure the following:

Option	Value
Supervision Frame	Choose Enabled . Supervision frames must be enabled for PRP/HSR to function.
Life Check Interval	Specify the interval between two successive supervision frames between 1 to 60 seconds, default 2.
Destination Address	Specify the Bridge Multicast Address used by your PRP/HSR networks in hex. This might be used when multiple PRP/HSR networks are visible at Layer 2 but not logically part of the same redundant domain. Ordinarily, all network devices in the same redundant domain should use the same multicast address.

Option	Value
Supervision Forward To Interlink	Choosing Enabled sends Supervision Frames over interlinks (ie LAN A, LAN B in PRP).

4. Click **Apply** to save changes.

Supervision frames can be monitored from **Redundancy > IEC 62439 > Supervision Frame**, and then selecting **Nodes Table**.

UI Setting	Description	Valid Range	Default Value
Node Forget Time	Specify the node forget time in seconds, which is how long a node entry will stay in the Nodes Table after the device stops receiving frames from the node.	60 to 120	60
<p>Note</p> <p>The Node Forget Time works as follows:</p> <ul style="list-style-type: none"> A timer starts/resets when the device receives any frame from a specific node. If the Node Forget Time expires without new frames from that node, the local device considers that node offline and removes it from the Nodes Table. <p>The Node Forget Time helps detect:</p> <ul style="list-style-type: none"> Node failures (e.g., a node powered off) Network issues (e.g., link failure on both LAN A and LAN B to that node) 			

Nodes Table

The screenshot shows a web interface for the Nodes Table. At the top left is a refresh icon. To its right is a search bar with a magnifying glass icon and the text "Search". Below the search bar is a table header with the following columns: "Index", "Node Type", "MAC Address", "Time Last Seen A (ms)", and "Time Last Seen B (ms)". Below the header, there is a pagination bar showing "Max. 1024" items, "Items per page: 50" (with a dropdown arrow), and "0 of 0" items. Navigation arrows for first, previous, next, and last are also present.

UI Setting	Description
Index	Shows the index of the node entry.
Node Type	Shows the node type according to IEC 62439-3 (DANP/RedboxP/VDANP/DANH/RedboxH/VDANH).
MAC Address	Shows the MAC address of the node.
Time Last Seen A (ms)	Shows the last time the device received packets from the node on LAN A.
Time Last Seen B (ms)	Shows the last time the device received packets from the node on LAN B.

 **Note**

The time between Time Last Seen A (ms) and Time Last Seen B (ms) should be the same or very close in a normally functioning network.

An increasing difference between the two times may be due to packets being dropped in one of the LANs, and may require further troubleshooting.

Layer 3 Redundancy

This section lets you configure the Layer 3 redundancy features of your device.

About VRRP

Virtual Router Redundancy Protocol (VRRP) is a network protocol enabling multiple switches to collaborate as a group and share a virtual IP address. The main purpose of VRRP is to provide redundancy for the default gateway utilized by hosts on a LAN or VLAN.

In a VRRP setup, a single switch is designated as the "master" while the other switches are "backup" switches. The master switch is responsible for forwarding packets sent to the virtual IP address. On the other hand, the backup switches supervise the master switch and take over its tasks in case of failure. This feature facilitates automatic failover and redundancy, guaranteeing network connectivity even in the event of a switch failure.

To sum up, here are some benefits of VRRP:

1. **Increased Network Reliability:** VRRP enables multiple switches to work together in a group, sharing a virtual IP address. This provides redundancy for the default gateway, ensuring that network connectivity is maintained even if one of the switches fails. This increases the overall reliability of the network and helps prevent downtime.
2. **Automatic Failover:** VRRP facilitates automatic failover, where backup switches take over the tasks of the master switch in case of a failure. This ensures that there is no disruption to network services and users can continue to access resources without any interruption.
3. **Easy Network Management:** VRRP simplifies network management by allowing multiple switches to work together as a group, sharing a virtual IP address. This

eliminates the need for complex routing protocols and reduces the risk of misconfigurations.

VRRP States

In VRRP, switches are assigned different roles and states to ensure seamless failover and improved network availability.

The three primary states of VRRP are:

- **Init State:** This is the initial state when a VRRP switch starts up. The switch initializes its VRRP configuration and has not yet determined whether it should become a Master or a Backup switch. The switch remains in the Init state until it starts receiving VRRP advertisements from other switches in the same VRRP group or until it begins sending advertisements itself.
- **Master State:** In this state, the switch is responsible for forwarding packets sent to the virtual IP address and acts as the default gateway for the devices in the network. The switch with the highest priority (or lowest IP address in case of a tie) becomes the Master switch. The Master switch periodically sends VRRP advertisements to the other switches in the VRRP group to maintain its role. If the Master switch fails, one of the Backup switches will take over the role based on priority.
- **Backup State:** Switches in the Backup state are waiting to take over the Master role if the current Master switch fails. Backup switches listen for VRRP advertisements from the Master and update their timers accordingly. If a Backup switch stops receiving VRRP advertisements from the Master switch for a certain period (typically three times the advertisement interval), it assumes that the Master switch has failed and attempts to transition to the Master state based on its priority.

The VRRP states ensure that the network has a functioning default gateway at all times, providing redundancy and improving network availability in case of device failure. By implementing VRRP, network administrators can achieve increased network reliability, automatic failover, and easier network management.

VRRP In Depth

VRRP enables several devices to share a virtual IP address and act as a unified virtual router. This feature provides backup capabilities in case one of the devices goes down or becomes unavailable. To accomplish this, VRRP group switches select a master switch based on priority, with the highest priority becoming the master. Each switch in the group announces its priority, and the master regularly sends out VRRP advertisements to the other switches to update its status.

The virtual IP address is linked with the VRRP group, and the master switch forwards network packets using the virtual IP address as the source address. The backup switches stay inactive, listening to the VRRP messages from the master and are ready to take over if the master fails. The master switch sends advertisement packets to the backup ones to inform them that it is still operational. The advertisement interval is manually configured. If the master switch fails, the backup switch is unable to receive advertisement packets from the master. Once the advertisement down timer expires, backup switch will realize that the master is experiencing issues or has powered down and one of the backup switches with a higher priority takes over as the new master, ensuring there is no disruption in network connectivity.

Note

1. The advertisement down timer is the time during which the Backup switch does not receive three consecutive advertisement packets from the Master.
2. The Backup switch will send GARP and advertisement packets to inform others that backup switch has become the new Master. After the switch update, their MAC tables are updated. (Refer to Figure. 2)
3. The VRRP standard protocol was defined in RFC 3768 and you can see the document on this website.
4. VRRP refers the active switch as the master and all other ones are in the backup state.
5. The virtual MAC address which is mapping to virtual IP is 00-00-5E-00-01-xx. (XX will depends on VRID.)
6. The master switch send the advertisement packet to 224.0.0.18 periodically in 1 second interval by default.

VRRP can also be set up to use preemption, which allows a higher-priority switch to take over as the master even if the current master device is still functional. This can be useful when the higher-priority switch is available again after a period of downtime.

In summary, VRRP is a valuable protocol that provides redundancy in network environments where high availability is critical. It enables multiple devices to act as a single virtual router, ensuring network traffic continues to flow in the event of a device failure.

VRRP

VRRP List

<input type="checkbox"/>	Enable	Interface	VRID	Priority	Virtual Router IP Address	Advertisement Interval	Preempt Mode	Preempt Delay	Accept Mode	Auth Type	Tracking ID	Decrement
<input type="checkbox"/>	Enabled	vlan1	4	2	192.168.127.250	30	Enabled	5	Enabled	None	--	--
<input type="checkbox"/>	Enabled	vlan1	3	2	192.168.127.252	30	Enabled	4	Enabled	Simple	--	--

Max: 40

UI Setting	Description
Enable	Shows whether the VRRP interface is enabled.
Interface	Shows which network interface is used for the VRRP interface.
VRID	Shows the virtual router ID for the VRRP interface, which is used to assign the virtual router to a VRRP group.
Priority	Shows the priority of the VRRP interface. Higher numbers indicate higher priority, with 254 being the highest.
Virtual Router IP Address	Shows the IP address of the VRRP interface.
Advertisement Interval (ms)	Shows the advertisement interval for the VRRP interface in milliseconds.
Preempt Mode	Shows the preemption status of the VRRP interface.
Preempt Delay	Shows the preempt delay value of the VRRP interface.
Accept Mode	Shows whether Accept Mode is enabled for the VRRP interface. When enabled, the virtual router designated as the master will allow others to access its own virtual IP address.
Auth Type	Shows the auth type of the VRRP interface, if VRRP V2 is being used.
Tracking ID	Shows the tracking ID of the VRRP interface.
Decrement	Shows the decrement value of the VRRP interface. Within a VRRP interface, the decrement feature dynamically adjusts the priority based on the status of tracked ports. If a tracked port becomes inactive (link down), the VRRP priority is reduced by a predefined decrement value. This ensures that a router with fewer active ports has a lower priority, minimizing the risk of a split brain scenario.

VRRP - Create Virtual Router

VRRP - Status

Menu Path: Redundancy > Layer 3 Redundancy > VRRP - Status

This page lets you see the status of your device's VRRP interfaces.

Interface	VRID	Priority	State	Master Address
0 of 0				

UI Setting	Description
Interface	Shows which network interface is used for the VRRP interface.
VRID	Shows the virtual router ID for the VRRP interface, which is used to assign the virtual router to a VRRP group.
Priority	Shows the priority of the VRRP interface. Higher numbers indicate higher priority.
State	Shows the state of the VRRP interface. <ul style="list-style-type: none"> • Init State: This is the initial state when a virtual router starts up. • Master State: The virtual router is acting as a master, and is responsible for forwarding packets sent to the virtual IP address and acting as the default gateway for the devices in the network. • Backup State: The virtual router is in the backup state, and waiting to take over the master role if the current master fails.
Master Address	Shows the IP address of the current master for the VRRP interface.

About Tracking

Tracking monitors connectivity status, and is leveraged by multiple redundancy protocols to trigger fallback actions. For example, when using the Virtual Router Redundancy Protocol (VRRP), tracking features can detect when the primary router becomes unavailable, triggering the backup router.

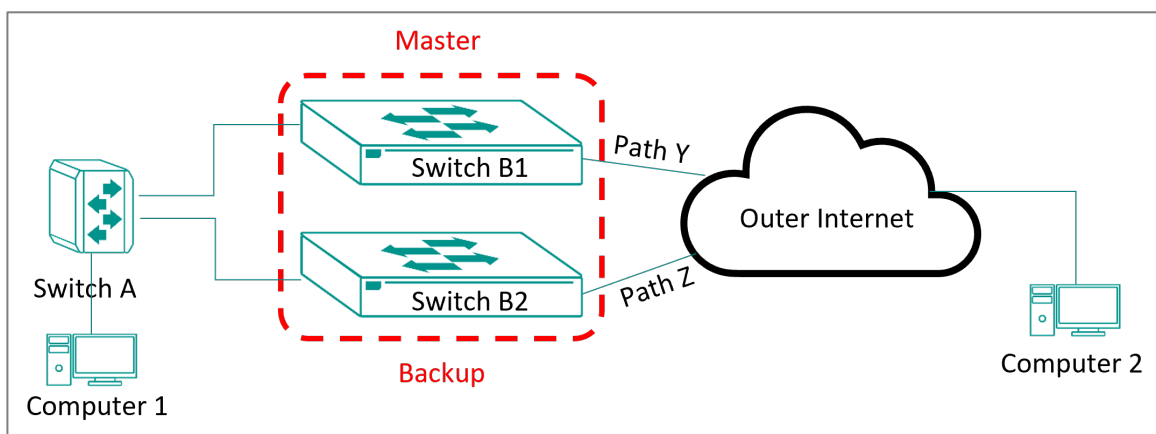

Tracking entries determine how tracking actions are triggered. The device supports three kinds of entries:

- **Interface tracking:** Monitors whether an interface or port is up or down.
- **Ping tracking:** Monitors whether a specified IP address responds to ping packets.
- **Logical tracking:** Compares the status of other tracking entries using AND, OR, NAND, or NOR operators.

Tracking operates at both Layer 2 and Layer 3.

Layer 3 Tracking: VRRP

VRRP is commonly used in conjunction with tracking for L3 switch redundancy. However, VRRP's tracking ability is limited to protecting traffic from L3 to L2, and cannot not track traffic from L3 to outside networks like the internet.

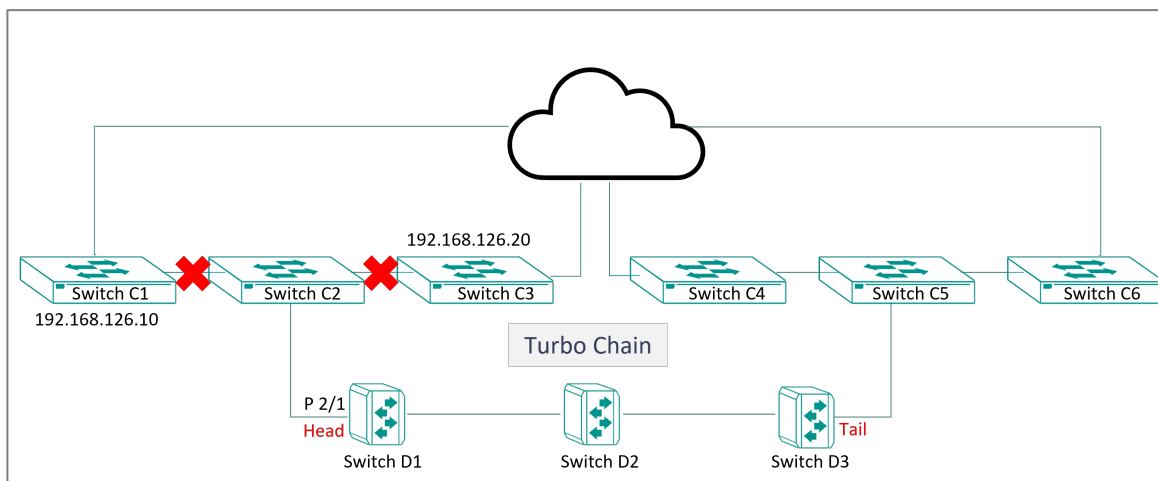

VRRP can protect traffic between L2 switches (Switch A) and L3 switches (Switches B1 and B2), but it cannot safeguard traffic from the L3 switches to the cloud. We can use a tracking to monitor **Path Y**, and if it fails, change the priority of the Master switch, rerouting through the backup switch and preventing disruption.

Layer 3 Tracking: Static Route

Static routes rely on manually configuring the next hop in the route. However, the state of the next hop may not always be known. To address this, ping tracking can monitor the IP address of the next hop, allowing the device to automatically disable the primary static route and move to a backup, ensuring that routes and subnets remain intact.

Layer 2 Tracking: Port Tracking

In Turbo Chain deployments, it can be hard to determine when pathways further than one level beyond the tail/head of the chain are down.

Turbo Chain only detects breaks in paths directly connected to the chain. With Tracking, we can expand this fault detection to monitor traffic from Switch C2 to Switches C1 and C3. If both paths are broken, Tracking can disable the port of Switch D1, triggering Turbo Chain to:

1. Change the head port of Switch D1 from forwarding to blocking
2. Change the tail port of Switch D3 from blocking to forwarding

This ensures that Turbo Chain doesn't maintain connections to switches that lack upstream connectivity.

Scenario: Configuring Interface Tracking for VRRP

Monitor connectivity to the outside internet to trigger VRRP (Virtual Router Redundancy Protocol).

1. On both switches, configure VRRP

At this stage, we set **Priority** values for the virtual routers: 250 for Switch B1 and 200 for Switch B2. The B1 **Priority** value will be decremented by the Tracking Entry

2. On Switch B1, Enable Tracking.
3. On Switch B1, create an interface tracking entry.

This entry will monitor Path Y connectivity to the internet.

4. On Switch B1, assign the **Tracking ID** to the Virtual Router.

This step will assign **Decrement** values to the tracking entry, which change the **Priority** values from Step 1. The reduced priority will cause Switch B2 to take priority over switch B1, routing all traffic over Path Z until Path Y is restored.

See the subsequent sections for examples and detailed instructions to configure this scenario.

Scenario: VRRP on Two Devices

In this scenario, we'll configure two devices connected to the same LAN (Local Area Network). We will configure VRRP to ensure that if one of the devices fails, the other device will continue to forward traffic to the LAN.

For example, suppose Device A (LAN interface IP: 192.168.127.1) is initially configured as the master and Device B (LAN interface IP: 192.168.127.2) as the backup in the VRRP group. Device A is responsible for forwarding packets to the LAN. The master should

keep tracking the interface by pinging the device (IP 192.168.127.100) in order to make sure of the LAN communication.

If Device A were to fail by ping lost or any link down event, Device B would detect this and assume the role of the master. It would then begin forwarding packets to the LAN, ensuring that there is no disruption in network connectivity. Once Device A becomes available, it can take over as the master, and Device B reverts to its backup role.

Example: Configuring VRRP on Device A

This task assumes that each device has already configured an interface called LAN1 with the following IP addresses:

- Device A: 192.168.127.1
- Device B: 192.168.127.2

To configure Device A, do the following:

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Layer 3 Redundancy > VRRP**, and then click **Settings**.
3. On the lower table of the screen, click **+ Add**.

The Create Virtual Router screen appears.

4. Configure the following, and then click **Create**.

Option	Value
Interface	LAN1
Virtual IP	192.168.127.3
Priority	200
Preemption	Enabled
Preemption Delay	120
Target IP	192.168.127.100

The **Virtual Router** settings appear in the list.

5. Under the Virtual Router list, click **Apply**.

6. At the top of the page, under **VRRP**, select **Enabled** from the dropdown list, and then click **Apply**.

Device A is now configured for VRRP.

Continue to configure Device B.

Example: Configuring VRRP on Device B

This task assumes that each device has already configured an interface called LAN1 with the following IP addresses:

- Device A: 192.168.127.1
- Device B: 192.168.127.2

To configure Device B, do the following:

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Layer 3 Redundancy > VRRP**, and then click **Settings**.
3. On the lower table of the screen, click **+ Add**.

The Create Virtual Router screen appears.

4. Configure the following, and then click **Create**.

Option	Value
Interface	LAN1
Virtual IP	192.168.127.3
Priority	100
Preemption	Enabled
Preemption Delay	120
Target IP	192.168.127.100

The **Virtual Router** settings appear in the list.

5. Under the Virtual Router list, click **Apply**.

6. At the top of the page, under **VRRP**, select **Enabled** from the dropdown list, and then click **Apply**.

Both devices are now configured for VRRP. In the event of a failure of one device, the other can take over using the same virtual IP address, ensuring continued function without reconfiguration.

Example: Creating an Interface Tracking Entry

Create an interface tracking entry to monitor port status and enable failover actions. You can select tracking entries from redundancy protocols to trigger backup or prioritization actions.

Make sure you assigned a **Tracking ID** in the previous task.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.
3. Next to **Tracking of...**, click **▼ Select**, choose **Interface**, and then click **+ Add**.
4. Configure all of the following, and then click **Create**:

Option	Value
Interface Tracking	Enabled
Tracking ID	1
Interface Type	Port
Port	1/1

The Interface Tracking Entry appears on the list.

Continue to add the interface tracking entry to the virtual router.

Example: Enabling Tracking

Turn on tracking to allow the system to monitor interfaces and trigger redundancy actions.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.
3. Set **Tracking** to **Enabled**, and then click **Apply**.

Example: Adding an Interface Tracking Entry to a Virtual Router

Add the tracking entry to a virtual router to enable automatic failover when connectivity is lost.

Make sure you assigned a **Tracking ID** in the previous task.

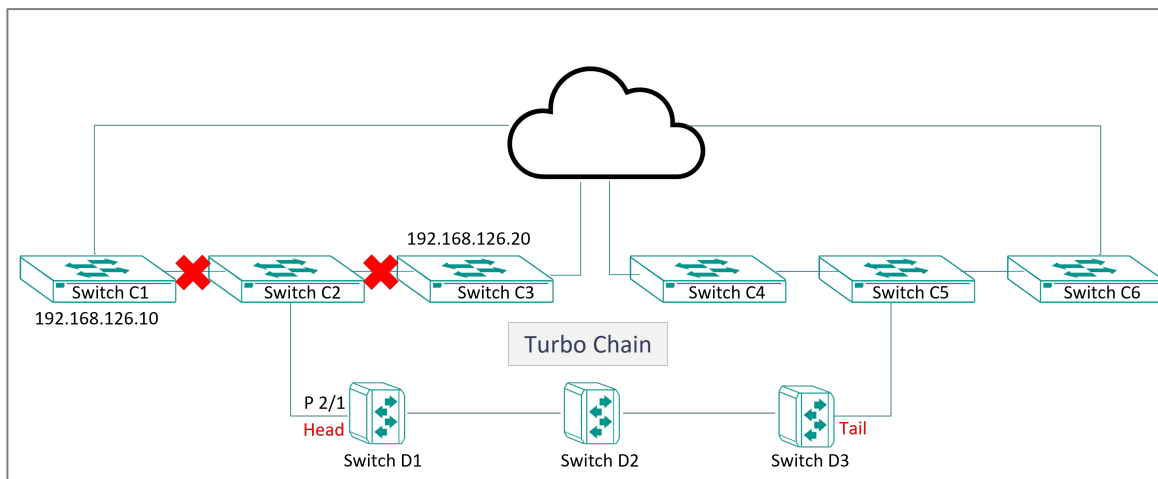

On Switch B1, do the following:

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Layer 3 Redundancy > VRRP**, and then click **Settings**.
3. Click  **Edit** next to the corresponding **Virtual Router**.
4. Click **Tracking ID**, and then choose the **Tracking ID** created in the preceding task, and then click **Select**.
5. Specify a **Decrement** of 100, and then click **Apply**.

The tracking entry allows changing to the backup virtual router. If an internet connection is no longer detecting, the **Decrement** value is subtracted from the **Priority** value of the virtual router, causing the backup to take over and restoring the network connection.

Scenario: Configuring Logical Tracking for Turbo Chain

In this example, we will create ping tracking entries on Switch D1 to monitor traffic by pinging two different target IP addresses. We will then combine these tracking entries by using a logical tracking entry, and use the logical tracking entry to control a port.

This task presumes that Turbo Chain has already been configured inline with the above scenario. Refer to About Turbo Chain for information about configuring Turbo Chain.

Configure all of the following on Switch D1:

1. Enable Tracking.
2. Create the Ping Tracking Entries targeting Switches C1 and C3.
3. Create Logical Tracking Entries using the Ping Tracking Entries.
4. Assign the Tracking ID to the Port from **Port Interface**.

Example: Enabling Tracking

Turn on tracking to allow the system to monitor interfaces and trigger redundancy actions.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.

3. Set **Tracking** to **Enabled**, and then click **Apply**.

Example: Creating Ping Tracking Entries

Create ping tracking entries to monitor IP reachability and support logical tracking for redundancy decisions.

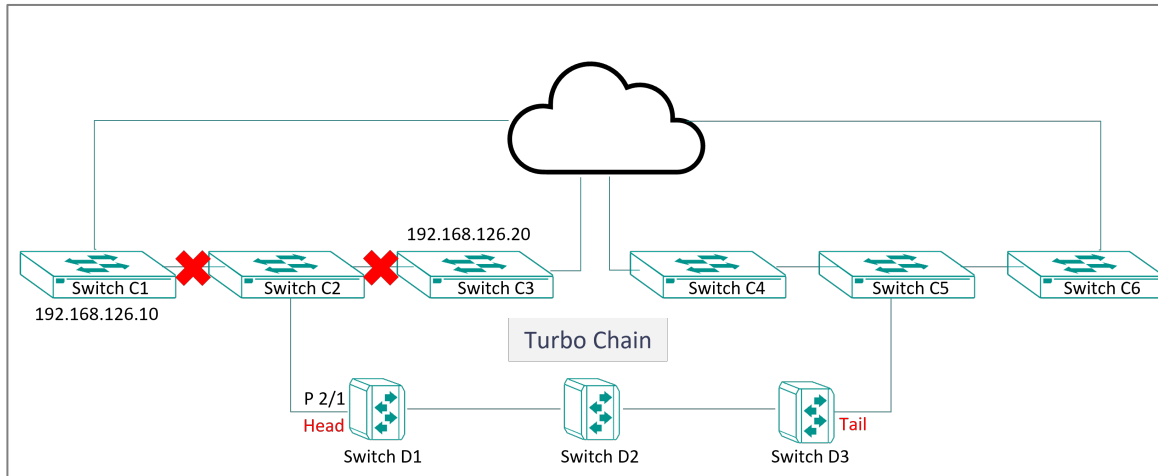

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.
3. Next to **Tracking of...**, click **▼ Select**, choose **Ping**, and then click **+ Add**.
4. Configure all of the following, and then click **Create**:

Option	Value
Ping Tracking	Enabled
Tracking ID	2
IP Address	192.168.126.10

5. Add a second entry by clicking click **+ Add**, specifying all of the following, and then clicking **Create**:

Option	Value
Ping Tracking	Enabled
Tracking ID	3
IP Address	192.168.126.20

These ping tracking entries separately monitor connectivity to C1 and C3.

Continue to create a logical tracking entry, which will combine the two ping tracking entries to determine when switch C2 is completely disconnected. The logical entry can then switch the Turbo Ring tail from blocking to forwarding, rerouting traffic over switch C5.

Example: Creating Logical Tracking Entries for Turbo Chain

Logical Entries are made up of one or more other kinds of tracking entries. These rules can accommodate more complex situations encompassing multiple tracking entries.

To combine the ping tracking entries 2 and 3 you just created:

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.
3. Next to **Tracking of...**, click **Select**, choose **Logical**, and then click **+ Add**.
4. Configure all of the following, and then click **Create**:

Interface Tracking	Enabled
Tracking ID	4
Logical List	Choose 2 and 3
Logical Operator	AND

Continue to assign tracking entries to ports.

Example: Adding Tracking Entries to Ports

Assign the logical tracking entry to a port to enable automatic failover if both routes fail.

Make sure you assigned a **Tracking ID** in the previous task.

On Switch B1, do the following:

1. Sign in to the device with administrator credentials.
2. Go to **Port > Port Interface > Port Settings**.
3. Next to **Port 2/1**, click  **Edit**.
4. Click **Tracking ID**, and then choose the **Tracking ID** created in the preceding task, and then click **Select**.
5. Click **Apply**.

Now that the logical tracking entry has been assigned, if both routes fail, the Turbo Chain tail can be triggered to allow traffic.

Scenario: Configuring Tracking for Static Route

Create an interface tracking entry to monitor an interface, then use that tracking entry to control a static route. Static routes offer fine control over traffic flows, but often suffer from a single point of failure. When coupled with Interface Tracking, static routes can be reconfigured based on network changes, without the complexity or unpredictability of dynamic routing.

This scenario requires a working static route. Refer to [Static Routes](#) for details about configuring static routes.

To configure this scenario:

1. Enable tracking.
2. Create an Interface Tracking Entry
3. Assign the Tracking Entry to the Static Route.

Example: Enabling Tracking

Turn on tracking to allow the system to monitor interfaces and trigger redundancy actions.

1. Sign in to the device with administrator credentials.

2. Go to **Redundancy > Tracking**.
3. Set **Tracking** to **Enabled**, and then click **Apply**.

Example: Creating an Interface Tracking Entry for a Static Route

Create an interface tracking entry to monitor port status and enable failover actions.

1. Sign in to the device with administrator credentials.
2. Go to **Redundancy > Tracking**.
3. Next to **Tracking of...**, click **▼ Select**, choose **Interface**, and then click **+ Add**.
4. Configure all of the following, and then click **Create**:

Option	Value
Interface Tracking	Enabled
Tracking ID	5
Interface Type	Network Interface
Network Interface	Select the interface to which the static route is bound

The Interface Tracking Entry appears on the list.

Continue to add the interface tracking entry to the Static Route.

Example: Adding Interface Tracking Entry to a Static Route

Add the tracking entry to a static route to disable the route automatically when connectivity is lost.

Make sure you assigned a **Tracking ID** in the previous task.

1. Sign in to the device with administrator credentials.
2. Go to **Routing > Unicast Route > Static Routing**.
3. Locate the Static Route to track, and then click **✎ Edit**.
4. Click **Tracking ID**, and then choose the **Tracking ID** created in the preceding task, and then click **Select**.
5. Click **Apply**.

The tracking entry will disable the static route when not available.

Tracking

Menu Path: Redundancy > Tracking

This page lets you manage the status tracking feature of your device.

This page includes these tabs:

- Settings
- Status

Tracking - Settings

Menu Path: Redundancy > Tracking - Settings

This tab lets you create and manage status tracking entries.

🔒 Limitations

You can create up to 16 tracking entries.

Tracking Settings

UI Setting	Description	Valid Range	Default Value
Tracking	Enable or disable status tracking for the device.	Enabled / Disabled	Disabled

Tracking List of Interface

If **Tracking List of Interface** is selected from the drop-down menu, this table will appear.

Tracking List of Interface ▾							
							
<input type="checkbox"/>	Tracking ID	Status	Interface	Down to Up	Up Delay (sec.)	Up to Down	Down Delay (sec.)
<input type="checkbox"/>	 1	Enabled	Port 1/1	Enabled	0	Enabled	0
<input type="checkbox"/>	 2	Enabled	vlan1	Enabled	10	Enabled	0

UI Setting	Description
Tracking ID	Shows the tracking ID for entry.
Status	Shows whether the entry is enabled.
Interface	Shows the interface monitored by the tracking ID.
Down to Up	Shows whether down to up state change is enabled for the entry. When enabled, the state for the tracking ID will change to Up if the interface status changes from down to up.
Up Delay (sec.)	Shows the delay in seconds the interface status must stay up to be detected as a down to up status change.
Up to Down	Shows whether up to down state change is enabled for the entry. When enabled, the state for the tracking ID will change to Down if the interface status changes from up to down.
Down Delay (sec.)	Shows the delay in seconds the interface status must stay down to be detected as an up to down status change.

Creating an Interface Tracking Entry

Menu Path: Redundancy > Tracking - Settings

Clicking the **Add (⊕)** icon on the **Redundancy > Tracking - Settings** page when **Tracking List of Interface** is selected will open this dialog box. This dialog lets you create a new interface tracking entry.

Click **CREATE** to save your changes and add the new entry.

Deleting an Interface Tracking Entry

Menu Path: Redundancy > Tracking - Settings

You can delete an entry by using the checkboxes to select the entries you want to delete, then clicking the **Delete** (🗑️) icon.

Tracking List of Ping

If **Tracking List of Ping** is selected from the drop-down menu, this table will appear.

Tracking List of Ping ▾									
<input type="checkbox"/>	Tracking ID	Status	IP Address	Interval (ms)	Timeout (ms)	Down to Up	Received (packets)	Up to Down	Lost (packets)
<input type="checkbox"/>	3	Enabled	192.168.127.26	1000	1000	Enabled	3	Disabled	3
<input type="checkbox"/>	4	Enabled	192.168.126.10	1000	1000	Enabled	5	Enabled	5

UI Setting	Description
Tracking ID	Shows the ID for the tracking rule.

UI Setting	Description
Status	Shows the status of the tracking rule.
IP Address	Shows the IP Address monitored by the tracking rule.
Interval (ms)	Shows the interval in milliseconds between state checks for the tracking rule.
Timeout (ms)	Shows the timeout in milliseconds to wait for the IP address to respond to a ping packet before detecting a timeout and setting the status to down.
Down to Up	Shows whether down to up state change is enabled for the entry. When enabled, the state for the tracking ID will change to Up if the IP address status changes from down to up.
Received (packets)	Shows the number of ping response packets that must be received before the status of the IP address changes to up.
Up to Down	Shows whether up to down state change is enabled for the entry. When enabled, the state for the tracking ID will change to Down if the IP address status changes from up to down.
Lost (packets)	Shows the number of ping request packets that must be lost before the status of the IP address changes to down.

Creating a Ping Tracking Entry

Menu Path: Redundancy > Tracking - Settings

Clicking the **Add (+)** icon on the **Redundancy > Tracking - Settings** page when **Tracking List of Ping** is selected will open this dialog box. This dialog lets you create a new ping tracking entry.

Lost	Specify the number of ping request packets that must be lost before the status of the IP address changes to down.	1 - 99	3

Deleting a Ping Tracking Entry

Menu Path: Redundancy > Tracking - Settings

You can delete an entry by using the checkboxes to select the entries you want to delete, then clicking the **Delete** () icon.

Tracking List of Logical

If **Tracking List of Logical** is selected from the drop-down menu, this table will appear.

UI Setting	Description
Tracking ID	Shows the ID for the tracking rule.
Status	Shows the status of the tracking rule.
Logical List	Shows the logical rule and the Tracking IDs it contains.

Creating a Logical Tracking Entry

Menu Path: Redundancy > Tracking - Settings

Clicking the **Add (+)** icon on the **Redundancy > Tracking - Settings** page when **Tracking List of Logical** is selected will open this dialog box. This dialog lets you create a new logical tracking entry.

Click **CREATE** to save your changes and add the new entry.

Deleting a Logical Tracking Entry

Menu Path: Redundancy > Tracking - Settings

You can delete an entry by using the checkboxes to select the entries you want to delete, then clicking the **Delete** () icon.

Tracking - Status

Menu Path: Redundancy > Tracking - Status

This page lets you see the status of your tracking entries.

Tracking Status List

You can use the drop-down menu at the top of the table to filter the list to show all tracking entries, or only tracking entries of a specific type.

Tracking ID	Status	Type	Interface/IP Address/Logical List	State	Time Since Last Change	No. of Changes
1	Enabled	Interface	Port 1/1	Down	0d8h16m5s	1
2	Enabled	Interface	vlan1	Up	0d0h44m0s	6
3	Enabled	Ping	192.168.127.26	Up	0d8h17m3s	0
4	Enabled	Ping	192.168.126.10	Down	0d8h15m59s	1
5	Enabled	Logical	[AND]1,3	Down	0d8h16m5s	1
6	Enabled	Logical	[NOR]2,4	Down	0d0h44m0s	7

UI Setting	Description
Tracking ID	Shows the tracking ID for entry.
Status	Shows whether the tracking ID enabled.
Type	Shows the type of the tracking entry.
Interface/ IP Address/Logical List	Shows the interface, IP address, logical list this entry is monitoring, based on the tracking entry's type.
State	Shows the current state of the tracking ID.
Time Since Last Change	Shows the time since the last state change for the tracking ID.

UI Setting	Description
No. of Changes	Shows the number of times the tracking ID has changed state since the device was booted.

Network Service

Menu Path: Network Service

This section lets you configure your device's network services.

This section includes these pages:

- DHCP Relay Agent
- DNS Settings

Network Service - User Privileges

Privileges to settings are granted to the different authority levels as follows. Refer to [System > Account Management > User Accounts](#) for more information on user accounts.

Settings	Admin	Supervisor	User
DHCP Relay Agent	R/W	R/W	R
DNS Settings	R/W	R/W	R

Configuring DHCP Server Functions

Moxa routers and L2 switches support DHCP server functionality, allowing auto-assignment of IP configurations.

Introduction to DHCP

The Dynamic Host Configuration Protocol (DHCP) automatically provides an Internet Protocol (IP) host with an IP configuration. This can include IP address, subnet mask, DNS Configuration, and default gateway. among others.

This ensures that connected clients do not need manual IP configuration, saving time and increasing flexibility in deployments.

Overview of DHCP Server Configuration

The integrated DHCP server of the device can operate in one of three modes.

DHCP Pool

This mode automatically assigns IP addresses to connected devices from a user-configured IP address pool.

MAC-based IP Assignment (Static IP)

MAC-based IP assignment, also known as static IP assignment, assigns specified IP addresses to MAC addresses of network devices. This ensures that devices maintain the same IP address, regardless of factors like connection order or lease duration. By configuring a DHCP server with table of MAC addresses and corresponding IP addresses, administrators can have more control over IP allocation, and by extension, device management and security.

Note

DHCP Pool and MAC-based IP Assignment can be active at the same time.

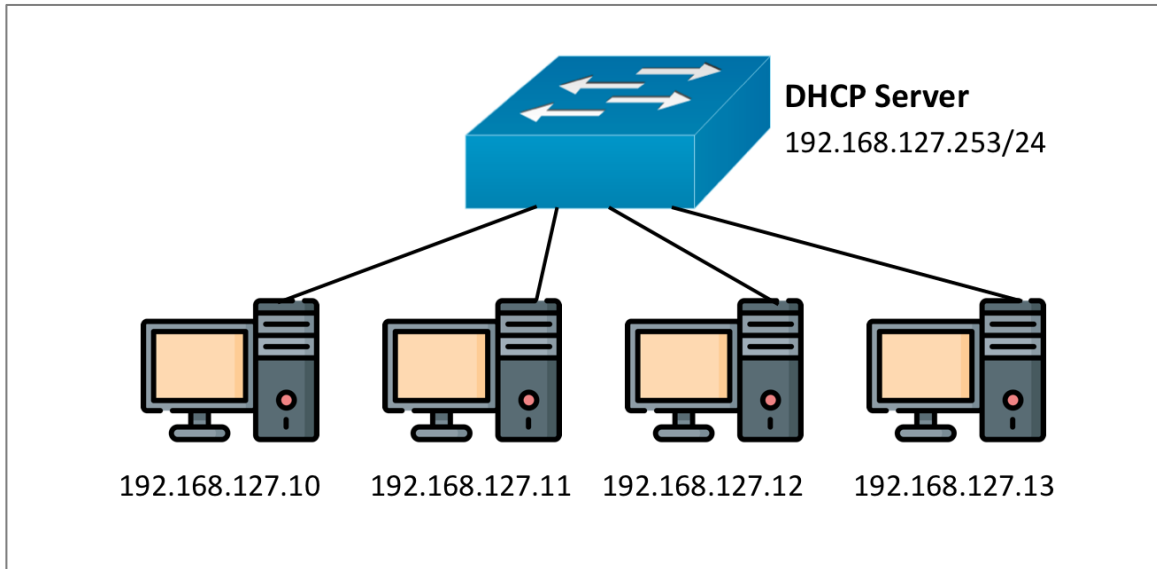

Port-based IP Assignment

Port-based IP assignment allocates IP addresses by the physical port on the device (Port 1, 2 etc.). This allows pre-assignment based on port, ensuring the device connected to each port will always have the same IP address.

Configuring Dynamic IP Address Assignment (DHCP Server Pool)

In this example, we configure a sample scenario with a pool of automatically-assigned IP addresses.

This scenario explains how automatically assign IP addresses to four PC clients on a subnet. We configure a switch act as DHCP server to automatically assign addresses, in In this scenario, the switch acts as a DHCP server for the 192.168.127.xxx IP subnet and PCs are DHCP clients.

1. Sign in to the device using administrator credentials.
2. Go to **System > Network > DHCP Server > General**.
3. Under **Mode**, make sure **DHCP/MAC-based IP Assignment** is selected.
4. Under DHCP Pool Table, click  **[Add]**.

The **Create a DHCP Server Pool** screen appears.

5. Configure all of the following:

Option	Value
Starting IP Address	192.168.127.10
Subnet Mask	24 (255.255.255.0)
Ending IP Address	192.168.127.20
Default Gateway	192.168.127.253
Lease Time	1440
DNS Server IP Address 1	8.8.8.8
DNS Server IP Address 2	8.8.8.4
NTP Server IP Address	8.8.8.10

6. Click **Apply** to save your settings.

Note

You can delete entries by going to System > Network > DHCP Server > General, and then under DHCP, selecting one or more entries by clicking the corresponding checkbox, and then clicking  [Delete].

Reserving IP Addresses for Specific Devices (MAC-based IP Assignment)

This scenario outlines how to reserve and automatically assign IP addresses for two cameras, ensuring that each camera always receives the same address.

We will configure the switch using MAC-based IP reservation and assignment.

1. Sign in to the device using administrator credentials.
2. Go to **System > Network > DHCP Server > General**.
3. Under **Mode**, choose **DHCP/MAC-based IP Assignment** from the drop-down list, and then click **Apply**.

4. Go to **System > Network Service > DHCP Server > MAC-based IP**

Assignment, and then click  **[Add]**.

The Create Entry screen appears.

5. Configure all of the following:

Option	Value
Enable	Enabled
Hostname	Camera1
IP Address	192.168.127.11
Subnet Mask	24 (255.255.255.0)
MAC Address	00:11:23:AA:BB:CC
Default Gateway	192.168.127.253
Lease Time	1440
DNS Server IP Address1	8.8.8.8
DNS Server IP Address1	8.8.8.4
NTP Server IP Address	8.8.8.10

The entry will appear in the table.

6. Repeat this process for the second camera, with the following settings:

Option	Value
Enable	Enabled
Hostname	Camera2
IP Address	192.168.127.12
Subnet Mask	24 (255.255.255.0)
MAC Address	00:11:23:AA:BB:CC

Option	Value
Default Gateway	192.168.127.253
Lease Time	1440
DNS Server IP Address1	8.8.8.8
DNS Server IP Address1	8.8.8.4
NTP Server IP Address	8.8.8.10

The entry will appear in the table.

 **Note**

You can delete entries by going to System > Network Service > DHCP Server > MAC-based IP Assignment, selecting one or more entries by clicking the corresponding checkbox, and then clicking  [Delete].

Configuring Port-based IP Assignment

This scenario assigns IP addresses to cameras based on their port of connection.

We will configure the switch as a DHCP server that uses port index-based IP assignments for each of the cameras. All ports will always assign the same IP addresses.

1. Sign in to the device using administrator credentials.
2. Go to **System > Network > DHCP Server > General**.
3. Under **Mode**, choose **Port-based IP Assignment** from the drop-down list, and then click **Apply**.
4. In the table below **Mode**, click  **[Add]**.
5. Configure all of the following:

Option	Value
Enable	Enabled
Port	7
IP Address	192.168.127.11
Subnet Mask	24 (255.255.255.0)
Default Gateway	192.168.127.253

Option	Value
Lease Time	1440
DNS Server IP Address1	8.8.8.8
DNS Server IP Address1	8.8.8.4
NTP Server IP Address	8.8.8.10
Hostname	Camera1

The entry will appear in the table.

6. Repeat this process for the second camera, with the following settings:

Option	Value
Enable	Enabled
MAC Address	00:11:23:AA:BB:CC
IP Address	192.168.127.12
Subnet Mask	24 (255.255.255.0)
Default Gateway	192.168.127.253
Lease Time	1440
DNS Server IP Address1	8.8.8.8
DNS Server IP Address1	8.8.8.4
NTP Server IP Address	8.8.8.10
Hostname	Camera2

The entry will appear in the table.

DHCP Server

Menu Path: Network Service > DHCP Server

This page lets you configure the DHCP server settings.

This page includes these tabs:

- General
- Lease Table

DHCP Server - General

Menu Path: Network Service > DHCP Server - General

This page lets you configure the DHCP server mode and port settings.

Limitations

You can create up to 256 DHCP/MAC-based IP assignments.

DHCP Server Settings - DHCP/MAC-based IP Assignment

If **Mode** is set to **DHCP/MAC-based IP Assignment**, and **DHCP Pool Settings** is **Enabled**, these settings will appear.

The screenshot shows a configuration form for DHCP/MAC-based IP Assignment. It includes a dropdown menu for Mode set to 'DHCP/MAC-based IP Assignment'. Under 'DHCP Pool Settings', the 'Enable' checkbox is checked and set to 'Enabled'. The form contains input fields for 'Starting IP Address *', 'Subnet Mask *', and 'Ending IP Address *'. Below these are fields for 'Default Gateway', 'Lease Time *' (with a value of 1.31622340 and unit 'sec.'), 'DNS Server IP Address1', 'DNS Server IP Address2', and 'NTP Server IP Address'. An 'APPLY' button is located at the bottom left of the form.

UI Setting	Description	Valid Range	Default Value
Mode	Select a DHCP server mode.	Disabled / DHCP/MAC-based IP Assignment / Port-based IP Assignment	Disabled
Enable	Enable or disable use of a DHCP pool.	Enabled / Disabled	Disabled
Starting IP Address	Specify the starting IP address of the DHCP IP pool.	Valid unicast IP address	N/A
Subnet Mask	Specify the subnet mask for DHCP clients in the pool.	Valid subnet mask	N/A
Ending IP Address	Specify the ending IP address of the DHCP IP pool.	Valid unicast IP address	N/A
Default Gateway	Specify the default gateway to use for DHCP clients in the pool.	Valid IP address	N/A
Lease Time	Specify how long in seconds a device can keep the assigned IP address before it needs to renew the lease with the DHCP server.	1 to 31622340	N/A
DNS Server IP Address1	Specify the IP address of the first DNS server to use for DHCP clients in the pool.	Valid IP address	N/A
DNS Server IP Address2	Specify the IP address of the second DNS server to use for DHCP clients in the pool.	Valid IP address	N/A
NTP Server IP Address	Specify the IP address of the NTP server to use for DHCP clients in the pool.	Valid IP address	N/A

DHCP Server List - DHCP/MAC-based Assignment

If **DHCP Server Mode** is set to **DHCP/MAC-based IP Assignment**, this table will appear.

Enable	Hostname	IP Address	Subnet Mask	Lease Time (sec.)	MAC Address	Default Gateway	DNS Server IP
Enabled	Test	19.126.255.5	255.255.192.0	6	00:90:E8:A9:ED:2B		

UI Setting	Description
Enable	Shows whether MAC-based IP assignment is enabled for the MAC address.
Hostname	Shows the hostname to use for clients that connect to the MAC address.
IP Address	Shows the IP address assigned to clients that connect to the MAC address.
Subnet Mask	Shows the subnet mask assigned to clients that connect to the MAC address.
Lease Time (sec.)	Shows the lease time in seconds for IP assignments through the MAC address.
MAC Address	Shows the MAC address of the MAC-based IP assignment.
Default Gateway	Shows the default gateway for clients that connect to the MAC address.
DNS Server IP Address 1	Shows the IP address of the first DNS server to use for clients that connect to the MAC address.
DNS Server IP Address 2	Shows the IP address of the second DNS server to use for clients that connect to the MAC address.
NTP Server IP Address	Shows the NTP server to use for clients that connect to the MAC address.

MAC-based IP Assignment - Creating a DHCP Server Entry

Menu Path: Network Service > DHCP Server - General

Clicking the **Add (+)** icon on the **Network Service > DHCP Server - General** page when **DHCP Server Mode** is set to **DHCP/MAC-based IP Assignment** will open this dialog box. This dialog lets you create a new MAC-based IP assignment.

Click **CREATE** to save your changes and add the new account.

Lease Table

Menu Path: [Network Service > DHCP Server - Lease Table](#)

This page lets you view the IP address lease table.

Lease Table

Hostname	IP Address	MAC Address	Time Left
	192.168.7.252		(static)

UI Setting	Description
Hostname	Shows the hostname of the client.
IP Address	Shows the IP address leased to the client.
MAC Address	Shows the MAC address of the client.
Time left	Shows the amount of time left in seconds on the DHCP lease for the client. (static) means the IP address is statically assigned.

Configuring DHCP Relay Agent

DHCP Relays can help reduce broadcast DHCP requests by relaying DHCP requests between networks.

About DHCP Relay Agents

DHCP relay agents can provide a bridge for DHCP communication across network segments.

DHCP Relays on L3 Switches

A DHCP Relay Agent on an L3 switch converts broadcast DHCP packets to unicast packets, and then routes them to the DHCP server.

DHCP Relays on L2 Switches

On an L2 switch, the switch would convert DHCP broadcast packets to DHCP unicast packets, forward them to an L3 switch, which would then route them to the DHCP server.

Configuring DHCP Relay Agent (RKS-G4000 Series)

You can configure your switch to serve as a DHCP relay agent.

1. Sign in to the device using administrator credentials.
2. Go to **Network Service > DHCP Relay Agent > General**.
3. Under **DHCP Relay Agent**, choose **Enabled** from the drop-down menu.
4. Specify up to 4 addresses in the **DHCP Server Address** field, and then click **Apply** to save changes.

Note

If DHCP Server Address is left blank, DHCP servers will be unable to reply to packets sent from connected clients.

5. To configure a **Port**, click the corresponding  **[Edit]** button.

6. The **Edit Port** screen appears.
7. Specify all of the following:

Option	Value
Relay	To enable the relay, choose Enabled . To disable the relay while retaining settings, choose Disabled .
Status	To accept incoming DHCP packets from DHCP servers, choose Trusted from the drop-down menu.

 **Note**

You can copy your settings to other ports by selecting them from the drop-down menu.

8. Click **Apply** to save your changes.

Configuring Option 82

Option 82 provides additional information in relayed packets that can make DHCP server address allocation more effective. If your DHCP server supports it, it can provide additional information that can facilitate context-aware address allocation, as well as more flexible tracking and management.

To configure Option 82:

1. Sign in to the device using administrator credentials.
2. Go to **Network Service > DHCP Relay Agent > General**, and then click **Option 82**.
3. Specify the ID that will be sent to the relay by clicking **Remote ID Type**, and then choosing an option from the drop-down menu.

For the **Other** option, you can specify a static value of up to 64 characters.

4. To enable **Option 82** on a given **Port**, click  **[Edit]** next to the corresponding **Port**.

Note

Choose an Port connected to client devices. Do not choose an outbound Port.

The **Edit Port** screen appears.

5. Click **Option 82** and choose **Enable** from the drop-down menu.
6. Click **Apply** to save your settings.

Clicking the **Edit** () icon for an port on the **Network Service > DHCP Relay Agent - Option 82** page will open this dialog box. This dialog lets you enable or disable Option 82 for the port.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
Option 82	Enable or disable Option 82 for the port.	Enabled / Disabled	Disabled
Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

About DNS

A Domain Name System (DNS) is a hierarchical decentralized naming system for computers, services, or other resources connected to the Internet or a private network. It translates domain names, which are human-readable identifiers for resources, into IP addresses, which are numerical identifiers used to locate and communicate with these resources.

DNS Settings

Menu Path: [Network Service](#) > [DNS Settings](#)

This page lets you specify the DNS servers your device will use. Click **APPLY** to save your changes.

DNS Settings

DNS Settings

Primary DNS Server

Secondary DNS Server

PIM-SM Settings	R/W	R/W	R
PIM-SM Status	R	R	R
Multicast Local Route	R/W	R/W	R
Multicast Routing Table	R	R	R

About Unicast Routes

A static route is a manually configured network path used to deliver network traffic to a specific destination network or host. Unlike dynamic routes established by routing protocols, static routes are created and managed by a network administrator. They are typically used in small networks or situations where there is a limited number of destinations that need to be reached.

Among these static routes, a special type known as the default route, or 'gateway of last resort', plays a critical role. This default route, often designated as 0.0.0.0/0, represents a catch-all path. When a device doesn't have a specific route for a packet's destination IP address, it will utilize the default route, sending the data along this path. This ensures that all data, regardless of its destination, has a route to follow.

While both default and static routes are manually configured, they serve different purposes. Static routes are used for specific, predefined network paths, while the default route is a catch-all, used when no other path is available for a specific data packet. This allows for increased control over network traffic while ensuring that data can reach otherwise unspecified networks, typically including the public Internet.

Static routes, including default routes, offer several advantages, including:

- More control over network traffic, allowing administrators to direct traffic along specific paths.
- Less overhead and resource usage, as static routes don't require routers to exchange routing information.
- Faster convergence, since there are no routing updates to process.

However, static routes also have some disadvantages:

- May be time-consuming and prone to human error, as administrators must manually configure and update routes.
- Unable to adapt to network changes automatically, requiring manual intervention to update routing tables when network topology changes.
- May not scale well in large networks with numerous destinations and frequent changes.

In summary, static routing is a method for unicast communication in which network paths are manually configured by network administrators. While they offer more control

over network traffic and can improve performance in some cases, static routes can be time-consuming to manage and may not be well-suited for large, dynamic networks.

Unicast Route

Menu Path: [Routing](#) > [Unicast Route](#)

This section lets you manage unicast routes for your device.

This section includes these pages:

- [Static Routing](#)
- [OSPF](#)
- [Routing Table](#)

Static Routing

Menu Path: [Routing](#) > [Unicast Route](#) > [Static Routing](#)

This page lets you manage static routes for your device, which allows you to specify the next hop (or router) that the device will forward data to for a specific subnet. Static routes will be added to the routing table and stored on the device.

Static Route List

	Destination	Netmask	Next Hop IP	Next Hop Interface	Distance	Tracking ID
<input type="checkbox"/>	192.168.122.2	255.255.255.254	---	vlan1	1	---

UI Setting	Description
Destination	Shows the destination IP address for the static route.
Netmask	Shows the subnet mask for the destination IP address.

UI Setting	Description
Next Hop IP	Shows the next hop IP on the path to the destination IP address.
Next Hop Interface	Shows the next hop Interface on the path to the destination IP address.
Distance	Shows the distance value used to determine the priority of the static route. Lower values have higher priority.
Tracking ID	Shows the tracking ID selected for the route. When the status of the tracking ID is up, the route will be enabled. When the status of the tracking ID is down, the route will be disabled.

Create a Static Route

Menu Path: Routing > Unicast Route > Static Routing

Clicking the **Add (+)** icon on the **Routing > Unicast Route > Static Routing** page will open this dialog box. This dialog lets you create a new static route.

Click **CREATE** to save your changes and add the new account.

OSPF

Menu Path: Routing > Unicast Route > OSPF

This section lets you manage OSPF for your device.

This section includes these pages:

- OSPF Settings
- OSPF Status

OSPF

Open Shortest Path First (OSPF) is a dynamic routing protocol used in Internet Protocol (IP) networks. Specifically, it is a link-state routing protocol in the group of interior gateway protocols, operating within a single autonomous system.

As a link-state routing protocol, OSPF establishes and maintains neighbor relationships in order to exchange routing updates with other routers. The neighbor relationship table is called an adjacency database in OSPF. OSPF forms neighbor relationships only with routers directly connected to it. In order to form a neighbor relationship between two routers, the interfaces used to form the relationship must be in the same area. An interface can only belong to a single area.

With OSPF enabled, the Moxa Layer 3 switch is able to exchange routing information with other L3 switches or routers more efficiently in a large system.

OSPF Settings

Menu Path: Routing > Unicast Route > OSPF > OSPF Settings

This page lets you configure OSPF for your device.

This page includes these tabs:

OSPF Status - Interface

Menu Path: Routing > Unicast Route > OSPF > OSPF Status - Interface

This page lets you view the status of your device's OSPF interfaces.

OSPF Status Interface List

Interface Name	Interface Alias	IP Address	Area	State	DR Router ID	BDR Router ID
vlan1		192.168.127.253	0.0.0.0	Down	N/A	N/A

Items per page: 50 1 - 1 of 1

UI Setting	Description
Interface Name	Shows the name of the interface this entry is for.
Interface Alias	Shows the alias for the interface.
IP Address	Shows the IP address for the interface.
Area	Shows the area ID for the interface.
State	Shows whether the interface is currently up or down.
DR Router ID	Shows the ID of the designated router (DR).
BDR Router ID	Shows the ID of the backup designated router (BDR).

OSPF Status - Neighbor

Menu Path: Routing > Unicast Route > OSPF > OSPF Status - Neighbor

This page lets you view the status of your device's OSPF neighbors.

OSPF Status Neighbor List

Neighbor ID	Priority	State	IP Address	Interface Name	Dead Interval (sec.)
-------------	----------	-------	------------	----------------	----------------------

UI Setting	Description
Neighbor ID	Shows the ID of the neighbor device.
Priority	Shows the L3 priority of the neighbor.
State	Shows the state of the neighbor.
IP Address	Shows the IP address of the neighbor device.
Interface Name	Shows which interface the neighbor is connected to.
Dead Interval (sec.)	Shows the dead interval in seconds for the neighbor.

OSPF Status - Database

Menu Path: Routing > Unicast Route > OSPF > OSPF Status - Database

This page lets you view the status of your device's OSPF database.

OSPF Status Database List

LSA Type	Area	Link ID	ADV Router	Age (sec.)
----------	------	---------	------------	------------

UI Setting	Description
LSA Type	Shows the type of the link state advertisement (LSA).
Area	Shows the area ID of the LSA.
Link ID	Shows the link ID of the LSA.
ADV Router	Shows the router where the LSA originated from.
Age (sec.)	Shows the age of the LSA in seconds.

OSPF Status - Virtual Link

Menu Path: Routing > Unicast Route > OSPF > OSPF Status - Virtual Link

This page lets you view the status of your device's OSPF virtual links.

OSPF Status Virtual Link List

Area	Router ID	Neighbor State	Events	LSA Retransmission Queue Length	Hello Suppressed
Items per page: 50 0 of 0 < < > >					

UI Setting	Description
Area	Shows the area ID for the virtual link.
Router ID	Shows the router ID for the virtual link.
Neighbor State	Shows the current state of the neighbor.
Events	Shows the number of events that have occurred since the device was booted. Events include the state of the virtual link changing and errors.
LSA Retransmission Queue Length	Shows the current length of the LSA retransmission queue.
Hello Suppressed	Shows whether hello messages to the neighbor are being suppressed.

Routing Table

Menu Path: Routing > Unicast Route > Routing Table

This page lets you see the current routing table for your device.

Type	Destination	Netmask	Next Hop	AD/Metric
Static	192.168.122.2	255.255.255.254	vlan1	1/1
Connected	192.168.127.0	255.255.255.0	vlan1	0/0
Connected	255.223.12.11	255.255.255.255	loopback1	0/0

UI Setting	Description
Type	Shows the source type of the route.
Destination	Shows the address of the destination network for the route.
Netmask	Shows the netmask of the destination network for the route.
Next Hop	Shows the IP address or interface of the next hop that the packet should be forwarded to.
AD/Metric	Shows the metric value/cost of the route to the destination network.

Note

Metrics are used to calculate the shortest path for data to travel through the network, and are determined by assigning cost values to the interfaces connecting to each router. The lower the cost value, the more the path will be preferred.

Multicast Route

Menu Path: Routing > Multicast Route

This section lets you configure and monitor the information about multicast routing protocols.

This section includes these pages:

- PIM-DM
- PIM-SM
- Multicast Local Route
- Multicast Routing Table

About PIM-DM

Protocol Independent Multicast - Dense Mode (PIM-DM) is a multicast routing protocol for dense networks. It operates by assuming all devices on the network want to receive multicast packets, and then accepts pruning requests for devices to opt-out. This is useful for high-density networks where bandwidth is plentiful and network distances are short.

PIM-DM is a Layer 3 multicast routing protocol, which interacts with IGMP Snooping to convert Class D (multicast) IP Addresses (224.0.0.0 to 239.255.255.255) into multicast MAC addresses to allow L2 addressing.

PIM-DM Mechanisms

PIM-DM uses three mechanisms to prevent excessive traffic:

- Flood and Prune: Initially, PIM-DM floods multicast traffic to all Layer 3 switches in the network. Layer 3 switches without interested receivers for multicast traffic send prune messages to their upstream neighbors, stopping further unwanted traffic.
- Periodic Flooding: To account for changes in group membership, PIM-DM periodically refloods the multicast traffic to ensure that new receivers have the opportunity to join the multicast group.
- Reverse Path Forwarding (RPF): PIM-DM uses RPF checks to prevent loops. A multicast packet is only accepted if it arrives on the interface that is the best route back to the source of the packet.

Enabling PIM-DM

Enable PIM-DM on the switch to support dense mode multicast routing on configured VLANs and interfaces.

- PIM-SM and Multicast Local Route must both be disabled.
- VLANs must have been created and assigned. Refer to [About VLAN](#).
- IGMP Snooping must be enabled for the interfaces

1. Sign in to the device with administrator credentials.
2. Go to **Routing > Multicast Route > PIM-DM**, and then click **Settings**.
3. Click **PIM-DM** and choose **Enable**, and then click **Apply**.

Note: All switches in the PIM-DM topology should be configured as PIM-DM mode, and should have same **State Refresh** and **State Refresh Interval** settings. Click **Apply** after changing these settings.

4. On the Interface Table, click  **Edit** corresponding to the interface.

The Edit Interface screen appears.

5. Click **PIM-DM** and choose **Enable**, and then click **Apply**.

You can enable PIM-DM on additional interfaces as needed.

To view Multicast Route Entries for PIM-DM, click **Neighbor** at the top of the screen.

PIM-DM

Menu Path: Routing > Multicast Route > PIM-DM

This page lets you manage PIM-DM for your device.

This page includes these tabs:

Expiration Time	Shows the time remaining before this multicast route is removed from the PIM-DM neighbor list if it is not refreshed.

About PIM-SM

Protocol Independent Multicast – Sparse Mode (PIM-SM) is a multicast routing protocol designed for environments where multicast receivers are sparsely distributed across the network. It assumes that only a very low percentage of receivers subscribe to a particular multicast group.

The key component of PIM-SM is the Rendezvous Point (RP), which forms the root of the multicast distribution tree. When multicast traffic starts flowing in a group, PIM-SM initially builds a multicast distribution tree rooted at the RP. However, this tree may not always provide the shortest path between the source and the receivers. It is configured to manage the initial distribution of multicast traffic. If a shorter path to the source is discovered, PIM-SM can perform a Shortest Path Tree (SPT) switchover to switch to a newly identified shortest path.

Since PIM-SM only forwards multicast data to the requester and always tries to route traffic through the shortest path, it is more scalable and efficient than PIM-DM.

PIM-SM RP Identification and Pathing # PIM-SM RP Identification and Pathing

PIM-SM follows a specific process to create and maintain paths.

Rendezvous Point (RP)

The RP plays a crucial role in PIM-SM. It is responsible for receiving multicast traffic from all sources and forwarding it down the multicast distribution tree to all receivers that have joined the multicast group. The RP can be statically configured or elected dynamically using a Bootstrap Router (BSR) mechanism.

Multicast Group Join Messages

When a host wants to receive multicast traffic for a specific group, the corresponding local router sends a PIM Join message to the RP. This message is propagated hop-by-hop until it reaches the RP, building a shared tree along the path.

Shortest Path Trees

Initially, multicast data is distributed along the shared tree, which is rooted at the RP and branches out to all receivers. For efficiency, once the first few packets have been received, routers close to the receivers may decide to switch from the shared tree to a source-specific shortest path tree (SPT).

The designated Layer 3 switch sends PIM Join messages directly towards the source of the multicast traffic, establishing the shortest path to the source. As the routers establish the SPT, Layer 3 switches in the longer path send PIM Prune messages to remove

themselves from the shared tree, ensuring that multicast traffic follows the most efficient path from the source to the receivers.

Tree Maintenance

Switches periodically send join messages to maintain their place in the tree and send Prune messages to leave the tree if they no longer need the multicast traffic, and to resolve which switch will forward multicast traffic on a given network segment, preventing duplicate packets by assert messages.

When a host no longer wants to receive multicast traffic, the switch sends a PIM prune message towards the RP or the source. If the source stops sending multicast traffic, the RP eventually times out the shared tree branches, and switches using the SPT will also time out their branches.

Configuring Non-RP Interfaces for PIM-SM

Enable PIM-SM on interfaces to participate in multicast routing without configuring the device as a Rendezvous Point (RP).

- PIM-DM and Multicast Local Route must both be disabled.
 - VLANs must have been created and assigned. Refer to [About VLAN](#).
 - IGMP Snooping must be enabled for the interfaces.
1. Sign in to the device with administrator credentials.
 2. Go to **Routing > Multicast Route > PIM-SM > PIM-SM Settings**, and then click **General**.
 3. Select **PIM-SM**, choose **Enabled**, and then click **Apply**.
 4. From the table of interfaces, locate the interface that will connect to the Static RP, and then click  **Edit**.

The Edit Interface screen appears.

5. Click **PIM-SM**, choose **Enable**, and then click **Apply**.

PIM-SM is now enabled. The device will participate in PIM-SM multicast routing using other RPs.

Designating a Static RP

Configure a static Rendezvous Point (RP) for PIM-SM by enabling multicast routing settings and defining RP parameters for multicast groups.

- PIM-DM and Multicast Local Route must both be disabled.
 - VLANs must have been created and assigned. Refer to [About VLAN](#).
 - IGMP Snooping must be enabled for the interfaces.
1. Sign in to the device with administrator credentials.
 2. Go to **Routing > Multicast Route > PIM-SM > PIM-SM Settings**, and then click **General**.
 3. Select **PIM-SM**, choose **Enabled**, and then click **Apply**.
 4. From the table of interfaces, locate the interface that will connect to the Static RP, and then click  **Edit**.

The Edit Interface screen appears.

5. Click **PIM-SM**, choose **Enable**, and then click **Apply**.
6. Go to **Routing > Multicast Route > PIM-SM > PIM-SM Settings**, and then click **RP**.
7. Under Static RP, click  **Add**.

The Create Static RP screen appears.

8. Specify all of the following, and then click **Apply**:

Option	Value
Group Address	Specify the PIM multicast group IP address.
Group Mask	Select the subnet mask of the group.
RP Address	Specify the IP address of the static RP for this multicast group.
Override	Enable or Disable the override function for the multicast group. When enabled, the static RP will be used before a dynamically learned BSR candidate if there is a conflict.

The Static RP appears on the list.

Designating a Dynamic RP Candidate

Configure the device as a dynamic RP candidate for PIM-SM by enabling BSR and specifying multicast group settings.

- PIM-DM and Multicast Local Route must both be disabled.
 - VLANs must have been created and assigned. Refer to [About VLAN](#).
 - IGMP Snooping must be enabled for the interfaces.
1. Sign in to the device with administrator credentials.
 2. Go to **Routing > Multicast Route > PIM-SM > PIM-SM Settings**, and then click **General**.
 3. Select **PIM-SM**, choose **Enabled**, and then click **Apply**.
 4. From the table of interfaces, locate the interface that will connect to the Static RP, and then click  **Edit**.
 5. Set both **PIM-SM** and **BSR Candidate** to **Enabled**, and then click **Apply**.
 6. Go to **Routing > Multicast Route > PIM-SM > PIM-SM Settings**, and then click **RP**.
 7. Under Candidate RP, click  **Add**
- The Create Candidate RP screen appears.
8. Configure the all of following, and then click **Apply**:

Option	Value
Group Address	Specify the multicast group(s) that this Candidate RP serves.
Group Mask	Specify the mask of the Group Address .
RP Interface Name (RP Address)	Specify the IP the device advertises as its RP address to other PIM routers.
RP Priority	Choose a value from 0 to 255. Lower numbers are high priority.

The selected RP will now be included in the candidate pool. You can view the current candidates under **Status** from **Routing > Multicast Route > PIM-SM > PIM-SM Settings**.

Type	Group Address	Group Mask	RP Address	Priority	Hold Time (sec.)	Expiration Time
0 of 0						

UI Setting	Description
Type	Shows the role type of this entry.
Group Address	Shows the group address of the BSR or RP this entry is for.
Group Mask	Shows the subnet mask of the group address.
RP Address	Shows the RP of this group address.
Priority	Shows the RP priority. Lower values have higher preference for the RP election process.
Hold Time (sec.)	Shows the hold time in seconds. The hold time is the amount of time a router will maintain the state information for this multicast group before deleting it due to inactivity.

UI Setting	Description
Expiration Time	Shows the time remaining before this multicast route is removed from the multicast routing table if it is not refreshed.

About Multicast Local Routes

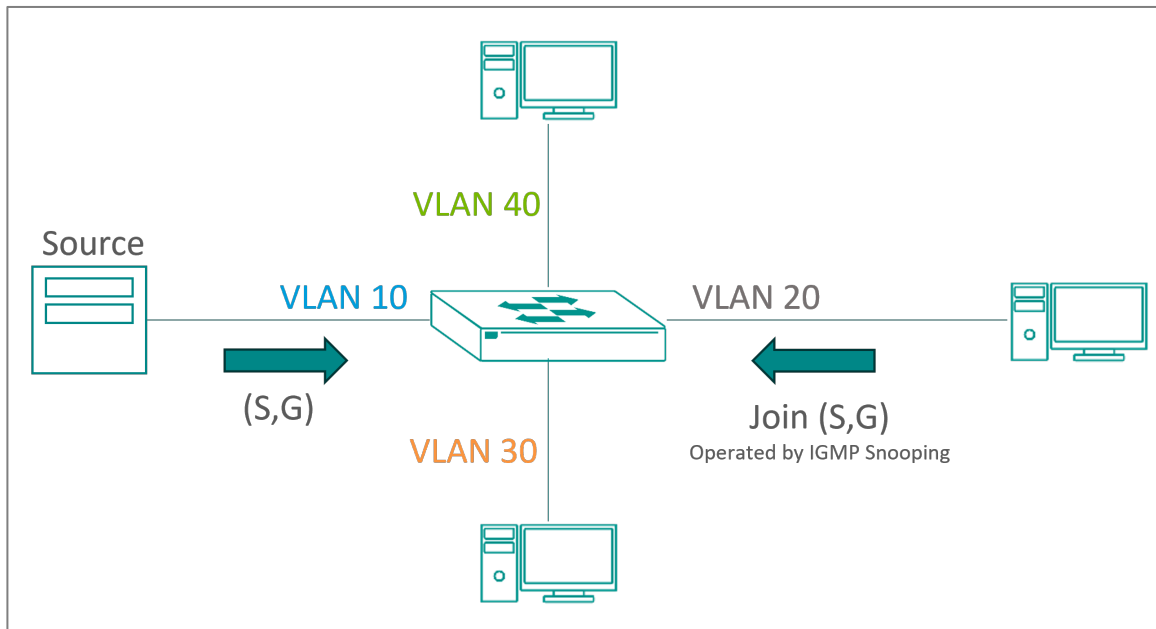

Multicast Local Routes—coupled with Multicast Access Control Lists— limit multicast traffic forwarding to multicast groups based on source and downstream VLAN settings. They enable precise control over multicast traffic within a network by allowing specific multicast streams to be permitted or denied.

Multicast Local Routes

Multicast Local Routes are entries created on the device that delineate multicast streams between VLANs. Once the traffic is identified, it can be managed with Multicast Access Control Lists. This kind of filtering is most effective when multicast source and destination VLANs are clearly defined.

Multicast Access Control Lists

The Multicast Access Control List, called Multicast ACL or MACL, determines whether to allow or block multicast streams (defined by the routes, above). The MACL checking sequence is prioritized based on MACL IDs, with smaller ID numbers having higher priority. If a multicast routing is filtered by a higher-priority MACL profile, lower-priority access control profiles will not be executed, ensuring that only the most critical routing decisions are applied.

Enabling Multicast Local Route

Multicast Local Route must be enabled before routes and MACs can take effect.

- Make sure PIM-SM and PIM-DM are disabled.
 - Make sure that you have created both Source and Downstream L3 VLAN interfaces.
 - Make sure IGMP Snooping on the interfaces is enabled.
1. Sign in to the device with administrator credentials.
 2. Go to **Routing > Multicast Route > Multicast Local Route**, and then click **General**.
 3. Set **Multicast Local Route** to **Enabled**, and then click **Apply**.

Note

Enable VRRP Master Only if you want to ensure that multicast traffic is forwarded only by the current VRRP master (if your topology uses VRRP). This helps prevent duplicate multicast streams and ensures consistent traffic flow in redundant configurations.

Configuring Multicast Routes

Define Multicast Local Routes to manage with Multicast Access Control Lists

1. Sign in to the device with administrator credentials.
2. Go to **Routing > Multicast Route > Multicast Local Route**, and then click **Routes**.
3. Click **+Add**, configure all of the following, and then click **Apply**:

Option	Value
Source VLAN	Specify the origin VLAN allowed to send multicast packets.
Destination VLAN	Specify the target VLAN allowed to receive multicast packets.

The multicast route appears on the table.

Configuring Multicast Access Control Lists (MACL)

Multicast Access Control Lists allow the creation of allowlists/blocklists for multicast routes.

1. Sign in to the device with administrator credentials.
2. To configure the Multicast Access Control List, go to **Routing > Multicast Route > Multicast Local Route**, and then click **MACL**.
3. Select **+Add**, and configure the following:

Option	Value
MACL ID	Choose an ID for the Access Control List. Lower numbers have higher priority in decisions.
Multicast Group	Specify a multicast group IP address. Serves as the "Destination" for the Access Control List entry.
Group Mask	Select a subnet mask for Multicast Group .
Source IP Address	Select the IP address from which the multicast packets originate.
Source IP Mask	Select a subnet mask for Source IP Address .
Source VLAN	Specify the source VLAN ID for Access Control List entry.

Option	Value
Downstream VLAN	Specify the downstream VLAN for the Access Control List entry.
Action	Select the action to take for this route. <ul style="list-style-type: none"> • Permit: Allow matching traffic • Deny: Drop matching traffic

4. Click **Create**.

Click **APPLY** to save your changes.

Login Policy Settings

UI Setting	Description	Valid Range	Default Value
Login Message	Specify the welcome message to display when users log in to the device.	0 to 500 characters	N/A
Login Authentication Failure Message	Specify the message to display if the user fails to log in. <div style="background-color: #fff9c4; padding: 5px; border: 1px solid #ccc;"> <p>⚠ Warning</p> <p>The Login Authentication Failure Message should not include information about passwords or other sensitive information.</p> </div>	0 to 500 characters	N/A
Account Login Failure Lockout	Enable or disable the lockout function, which will temporarily prevent users from logging in for the Lockout Duration after the Retry Failure Threshold is exceeded. This can be useful for preventing brute force attacks.	Enabled / Disabled	Disabled

UI Setting	Description	Valid Range	Default Value
Retry Failure Threshold	Specify the number of login retry attempts allowed before the user is locked out for the Lockout Duration .	1 to 10	5
Lockout Duration	Specify the lockout duration in minutes during which a locked-out user will be unable to log in.	1 to 10	5
Auto Logout After	Specify the amount of time in minutes a user can be idle before they will be automatically logged out from the device.	0 to 1440	5

About Trusted Access

Trusted Access is a feature that allows device management only from trusted IP addresses that you specify.

Trusted access is a crucial mechanism for maintaining the security and integrity of your network infrastructure. It ensures that only authorized devices can connect to sensitive network resources, reducing the risk of unauthorized access and potential security breaches.

Why Trusted Access Matters

- **Security:** By allowlisting IP addresses, administrators ensure that only devices with approved IP addresses can access the network configuration, helping to prevent unauthorized connections.
- **Access Control:** Trusted access enables administrators to define which IP addresses can connect to sensitive resources, ensuring that only trusted devices interact with critical areas of the network.

How Trusted Access Works

Enabling trusted access on a device involves configuring IP allowlists. Once an IP address is allowlisted, the device treats it as trusted, allowing access to device management functions. Devices not on the allowlist are denied access, helping to maintain a secure and controlled network environment.

Example: Configuring and Enabling Trusted Access

Enable trusted IP address settings to only allow users to access network device management features from IP addresses you choose. Only IPv4 addresses are supported.

Make sure you add all management devices to the allowlist before enabled Trusted Access, otherwise you may lose access to the management console.

To configure trusted access, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Security > Device Security > Trusted Access**, and then click  **[Add]**.

The Create Entry screen appears.

3. Specify the **IP Address** and **Subnet Mask** of the device to add the device IP to the allowlist, and then click **Create**.

The specified **IP Address** and **Netmask** appear on the Trusted Access list.

4. Once you have created entries for all devices, under **Trusted Access**, choose **Enabled**, and then click **Apply**.

Trusted access will now be enabled, and only devices on the allowlist will be able to access management features.

Trusted Access

Menu Path: **Security > Device Security > Trusted Access**

This page lets you limit access to the device to trusted IP addresses you specify. You can also limit access to the device to LAN connections only.

⚠ Limitations

You can create up to 20 trusted IP entries.

About SSH & SSL

SSH and SSL are security protocols.

- **Secure Shell (SSH):** SSH is the recommended protocol for secure command-line access. This protocol encrypts the communication channel between a user and a device's management interface. This helps ensure that any data exchanged—like usernames, passwords, or configuration commands—remains hidden from eavesdroppers on the network.
- **Secure Sockets Layer (SSL):** While functionally similar to SSH, SSL is often used for web-based applications. Though the term "Secure Sockets Layer (SSL)" is still commonly used, it's important to note that it's been deprecated in favor of the more secure Transport Layer Security (TLS) protocol. In the context of Ethernet switches, some may offer a web interface for management tasks. Moxa switches support TLS versions 1.2 and 1.3. TLS encrypts the communication channel between a user's web browser and a device's web interface. This ensures the security of sensitive data during remote configuration tasks performed through the web interface.

Note

Certificates: Self-signed vs. Trusted

There are two main types of certificates used for TLS connections: self-signed certificates and trusted certificates.

- **Self-signed certificates:** These certificates are issued by the device itself and are not verified by a third-party Certificate Authority (CA). While they provide basic encryption, they may generate warnings in web browsers due to the lack of trust verification.
- **Trusted certificates:** These certificates are issued by a trusted CA and are generally considered more secure. Web browsers readily accept connections secured with trusted certificates.

The choice between self-signed and trusted certificates depends on your specific security requirements.

SSH & SSL

Menu Path: Security > Device Security > SSH & SSL

This page lets you manage your SSH key and SSL certificate.

This page includes these tabs:

- SSH
- SSL

SSH

Menu Path: Security > Device Security > SSH & SSL - SSH

This page lets you manage your device's SSH key.

Note

Regenerating your SSH key regularly strengthens SSH security by invalidating potentially compromised keys and adding another layer of defense against unauthorized access. There's no one-size-fits-all answer for how often to regenerate keys; it depends on security risk factors like server importance, access frequency, and potential exposure. Consider regenerating them every few months or every year, especially for critical servers.

- Access Control List
- Network Loop Protection
- Binding Database
- DHCP Snooping
- IP Source Guard
- Dynamic ARP Inspection

About IEEE 802.1X

IEEE 802.1X is a standard for managing access control, ensuring that devices seeking to access network resources are what they claim to be.

About IEEE 802.1X

802.1X is a standard for port-based Network Access Control (NAC) that provides an authentication framework for devices trying to connect to a network.

Part of the IEEE 802.1 group of networking protocols, the primary purpose of 802.1X is to enhance the security of wired and wireless networks by requiring users and devices to authenticate themselves before gaining access to network resources.

Topology

An 802.1X topology has three roles:

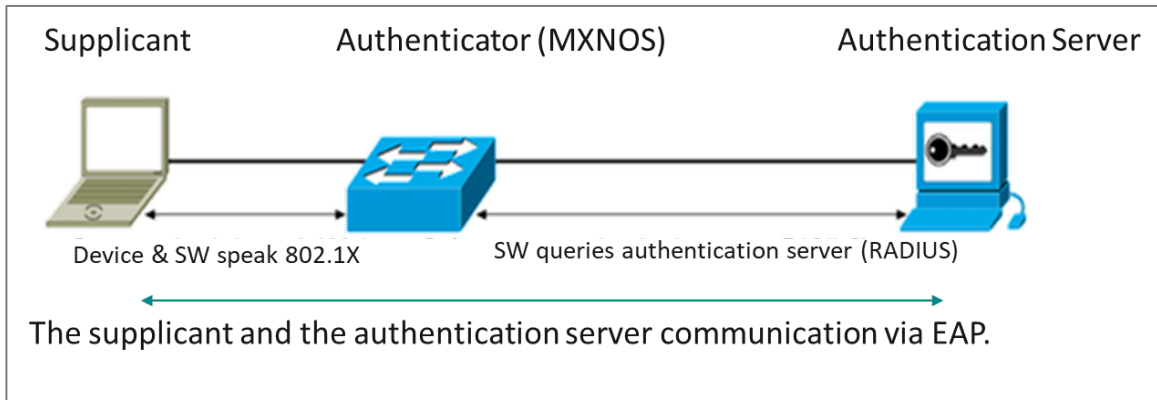

- **Supplicant:** The client device (e.g., laptop, smartphone) seeking network access.
- **Authenticator:** The network device (e.g., switch, wireless access point) that controls access to the network ports.
- **Authentication Server:** A server that performs the actual authentication of the supplicant. It could be a RADIUS (Remote Authentication Dial-In User Service) server or another centralized authentication service.

Note

In an 802.1X environment, Moxa switches primarily function as authenticators. However, they can also be optionally configured to act as authentication servers.

In an 802.1X authentication system, the supplicant (client), authenticator device (Switch or Wi-Fi AP), and authentication server exchange information using the Extensible Authentication Protocol (EAP).

A supplicant and an authenticator exchange EAPOL (Extensible Authentication Protocol over LAN) frames with each other. We can either use an external RADIUS server as the authentication server or implement the authentication server in the Moxa switch by using a Local User Database as the authentication look-up table. When using an external RADIUS server as the authentication server, the authenticator and the authentication server exchange EAP frames.

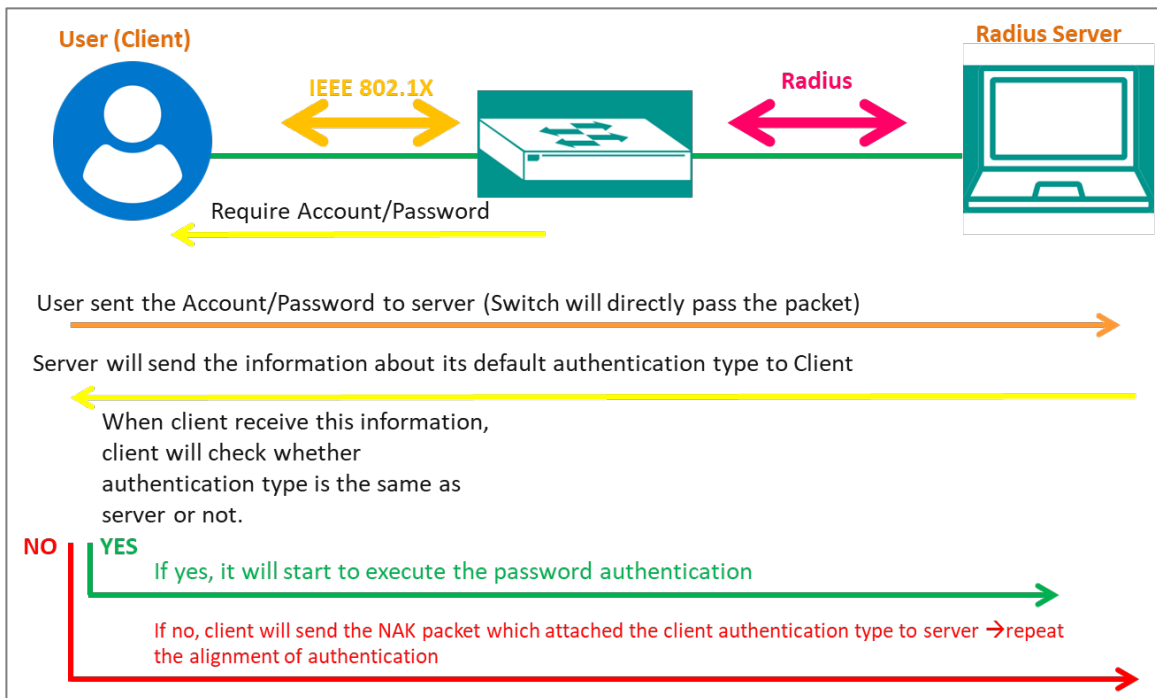

Note

It is possible to use 802.1X authentication without a separate authentication server using local authentication. The Authenticator can be configured to determine client access rights.

Authentication Process

When a device connects to a network port configured for 802.1X, the following process occurs:

1. Initialization: The supplicant sends an EAPOL (Extensible Authentication Protocol Over LAN) start message to the authenticator.

2. **Authentication Request:** The authenticator replies with an EAP Request/Identity message, prompting the supplicant to provide its identity.
3. **Identity Response:** The supplicant responds with its identity, typically a username.
4. **Authentication Exchange:** The authenticator relays the identity to the authentication server, which then initiates an authentication exchange with the supplicant using EAP (Extensible Authentication Protocol).
5. **Authentication Result:** Based on the outcome of the authentication process (which could involve methods like username/password, digital certificates, or other credentials), the authentication server sends an Accept or Reject message to the authenticator.
6. **Access Granted/Denied:** If authentication is successful, the authenticator allows the supplicant access to the network. If authentication fails, access is denied.

802.1X provides a robust mechanism for controlling network access, ensuring that only authorized users and devices can connect to the network. It's widely used in enterprise environments to enforce security policies and protect against unauthorized access. The following diagram illustrates the process of a client establishing 802.1X communication with the authentication server through the MXNOS switch.

Note

Authentication can also be initiated by the authenticator. Ordinarily, supplicants initiate the authentication process, with an EAPOL-Start frame sent to the authenticator. When the authenticator initiates the authentication process (either on its own, or on receipt of an EAPOL-Start frame), it sends an EAP Request/Identity frame to ask for the username of the supplicant.

802.1X Radius

■ Typical Structure

802.1X Local

■ Typical Structure

Example: Configuring a Switch as an Authenticator

In this example, we configure a Moxa switch as an authenticator, connecting supplicant devices (2 cameras and a computer) to a RADIUS server.

Our sample topology should look like the following:

The topology uses the following roles:

- Supplicants:
 - Cameras 1 and 2, connected to the switch with a hub on port 8
 - Computer, connected on Port 7
- Authenticator: Switch
- Server: RADIUS server

Before you begin: This task uses sample values and assumes that a RADIUS server is already configured.

To configure the switch as an authenticator, do the following:

1. Sign in to the device using administrator credentials.
2. Got to **Security > Network Security > IEEE 802.1X**→**General**.
3. Click **IEEE 802.1X** and choose **Enabled** from the drop-down menu.
4. Click **Authentication Mode**, choose **RADIUS** from the drop-down menu, and then click **Apply** to save your settings.
5. To configure the example computer, click  **[Edit]** corresponding to **Port 7**.
Result: The **Port Settings** screen appears.
6. Configure the following:

7.

Option	Value
Enabled	Enabled
Port Control	Auto
Authentication Session Type	Port-Based
Max. Request	2
Quiet Period	60
Reauthentication	Disabled

8. Click **Apply**.

9. To configure the example cameras, click  **[Edit]** corresponding to **Port 8**.

Result: The **Port Settings** screen appears.

10. Configure the following:

Option	Value
Enabled	Enabled
Port Control	Auto
Authentication Session Type	MAC-based
Max. Request	2
Quiet Period	60
Reauthentication	Disabled

11. Click **Apply**.

What to do next: You must configure RADIUS server settings before the switch can function as an authenticator.

Example: Configuring RADIUS Server Settings

The switch must be configured with the RADIUS server settings before it can serve as an authenticator.

1. Sign in to the device using administrator credentials.
2. Go to **Security > Network Security > IEEE 802.1X > RADIUS**.
3. Specify all of the following:

Option	Value
Server IP Address 1	192.168.127.11
Auth Port	1812
Share Key	Type your key here
Timeout	5
Retransmit	5

4. Click **Apply** to save changes.

About MAC Authentication Bypass

MAC Authentication Bypass (MAB) allows network access based on a device's Media Access Control (MAC) address, bypassing traditional username/password authentication methods like 802.1X. This feature is particularly useful for granting access to devices that cannot support more advanced authentication protocols.

How MAC Authentication Bypass Works

MAB operates like a VIP list for your network. When a device connects, the network checks its MAC address against an approved list. If the MAC address is recognized, the device is granted access without needing additional authentication. If the MAC address isn't on the list, access is denied.

When to Use MAB

- **Legacy Devices:** Some older devices may not support advanced authentication methods like 802.1X. MAB provides a way to allow these devices to connect using their MAC address.

While MAB is convenient, it's important to note that MAC addresses can be spoofed, making this method less secure compared to more robust authentication techniques. Therefore, MAB should be used in scenarios where ease of access is prioritized over stringent security measures.

Configuring MAC Authentication Bypass

To add a device to MAC Authentication Bypass, first add the MAC address of the bypass device to the **Local Database**, then enable **MAC Authentication Bypass** on the Port the bypass device is attached to.

This procedure assumes that devices on your network are authenticated using either a RADIUS server or a local database.

Note

MAC addresses are easily spoofed, and are not generally accepted as adequate means of authentication without other forms of security. Make sure that you have fully evaluated the security risks associated with this feature before use in a sensitive environment.

To configure MAC Authentication Bypass, do the following:

1. Sign in to the device using administrator credentials.
2. Go to **Security > Network Security > MAC Authentication Bypass**, click on the **Local Database** tab, and then click  **[Add]**.

The Create Entry screen appears.

3. Specify the **MAC Address** of the device to be added to the local database, and then click **Create**.

The MAC address appears in the table.

4. Click the **General** tab at the top of the screen, and verify that **MAC Authentication Bypass** is **Enabled**.
5. Locate the port the bypass device is attached to, and then click the corresponding  **[Edit]** button.

The Edit Port Settings screen appears.

6. Set **MAC Authentication Bypass** to **Enabled**, and then click **Apply**.

The bypass device will now be authenticated for network access.

About MAC Security

Media Access Control Security (MAC security) is defined in IEEE802.1AE and 802.1X, specifying how to secure data communication over a Local Area Network (LAN). MAC security ensures data is securely sent and received at the MAC layer by providing data integrity checks, data origin authentication, and confidentiality.

MAC security cryptographically protects frames on a hop-by-hop basis at Layer 2 on LAN and can be enabled as in combination with other end-to-end Layer 3 security technologies such as IPsec, Secure Sockets Layer (SSL), Transport Layer Security (TLS), and Secure Shell Protocol (SSH).

MAC Security In-Depth

For data exchanged between devices in a LAN, MAC security ensures transmission security using cryptographic technology in the MAC layer.

MAC security involves two standards: IEEE802.1AE and 802.1X. The frame format for data encapsulation, encryption, and authentication is defined in IEEE802.1AE. MACsec Key Agreement (MKA), a key management protocol, is defined in IEEE 802.1X-2010. MKA provides agreement for MAC security policy and key generation mechanisms to extend and optimize the original 802.1X protocol.

MAC security operation starts by using a Pre-shared Key (PSK) to authenticate a peer switch. One switch is designated as the Key Server and the other switch as the Key Client. The Key Server and Key Client share the same user-specified connectivity Association Key Name (CKN) and Connectivity Association Key (CAK). The Key Server uses the CAK to generate a Secure Association Key (SAK) and distribute it to the Key Client to form a secure association. Data exchanged between the peer switches in the path will then be encrypted.

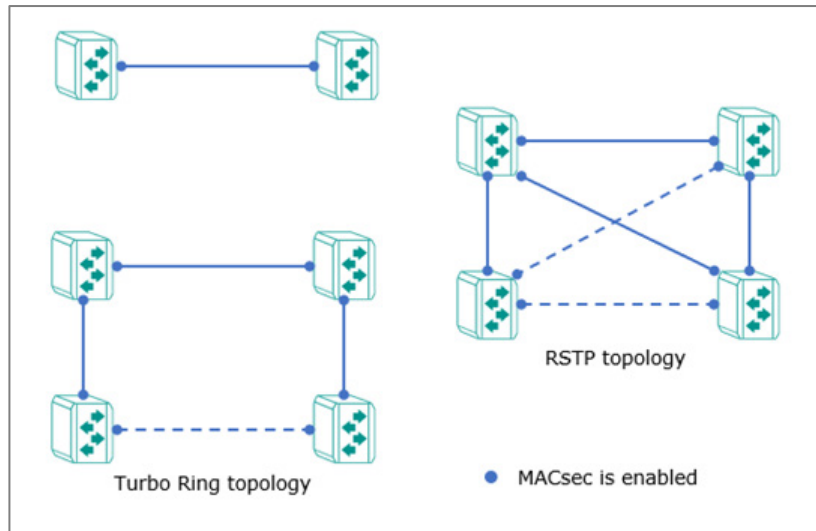

To ensure data traffic is transmitted securely, all data traffic ports must enable MAC security.

MAC Security with Redundancy Protocols

When running MAC security with Redundancy Protocols, make sure of the following:

- For Turbo Ring topologies, all ring ports must enable MAC security.
- For RSTP topologies, all redundant ports must enable MAC security.

Configuring MAC Security

MAC security must be configured on each relevant port and device to protect data.

To configure MAC security, do the following:

1. Sign in to the device with administrator credentials.
2. **Security > Network Security > MAC security**, and then click **Settings**.
3. To enable **MAC security**, under **MAC security** choose **Enabled** from the dropdown menu, and then click **Apply**.
4. To configure MAC security on a given port, click the corresponding  **[Edit]** and then configure all of the following:

Option	Value
Status	Enabled
Participant CKN	Specify a Connectivity association Key Name of 1-16 characters.

Option	Value
Participant CAK	Specify a Connectivity association Key of 1-16 characters.
Key Server	<ul style="list-style-type: none"> • Enabled: The port is a key server. • Disabled: The port is a key client.

 **Note**

- The CKN/CAK must match the connected port on the peer switch.
- One CKN and one CAK per port.
- CKNs/CAKs should not be reused on the same device.
- Valid CKN/CAK characters: a-z, A-Z, numbers 0-9, special characters @%^*()-_+={}[]:~\$` , and do not permit whitespaces.
- CKNs/CAKs must be configured in pairs, and cannot be partially configured (such as configuring one, but not the other).
- Deleting a CKN/CAK may also delete its corresponding CAK/CKN.

5. Click **Apply** to save your changes.

Make sure to enable MAC security on all relevant devices and ports.

MAC Security

Menu Path: [Security](#) > [Network Security](#) > [MAC Security](#)

This page lets you manage MAC security for your device.

This page includes these tabs:

About Static Port Lock

Static Port Lock provides port-based security by letting you specify which device MAC addresses are allowed to access the network through a specific port. Packets sent from unknown devices or from configured devices with mismatching ports will be dropped. In other words, only packets from devices with allowed MAC addresses can be sent to the specific port, helping secure network data transmissions.

Static Port Lock

Menu Path: Security > Network Security > Port Security - Static Port Lock

This page lets you configure Static Port Lock.

Note

This tab will only appear when Port Security Mode is set to Static Port Lock.

Limitations

You can create up to 1024 static port lock entries.

Max. 1024 Items per page: 50 1 - 1 of 1

UI Setting	Description
Port	Shows the port number the entry is for.
VLAN ID	Show the VLAN applied to the port.
MAC Address	Show the MAC address of the device which is used as a reliable source for network access.
Type	Shows how the entry was created.
Effective	Shows whether the entry is effective.

Note
If an entry is not effective, it may have an invalid interface set for it.

Static Port Lock - Add Entry Settings

Menu Path: [Security](#) > [Network Security](#) > [Port Security - Static Port Lock](#)

Clicking the **Add** () icon on the **Security > Network Security > Port Security - Static Port Lock** page will open this dialog box. This dialog lets you configure static port lock settings for a port.

Click **CREATE** to save your changes and add the new account.

Edit Entry Settings

Port *

VLAN ID *

MAC Address * 

UI Setting	Description	Valid Range	Default Value
Port	Select the port to add an entry for.	Drop-down list of ports	N/A
VLAN ID	Specify the VLAN ID to use with the port.	Valid VLAN ID	N/A
MAC Address	Specify the MAC address of the device that will be used as the reliable source for network access.	Valid MAC address	N/A

About MAC Sticky

MAC Sticky is a function that allows you to configure the maximum number of MAC addresses that a port can "learn." You can also configure what action should be taken when a new MAC address tries to access a port after the maximum number of MAC addresses have already been learned.

How MAC Sticky Works

In MAC Sticky mode, you can set a proper limit number and then configure trusted devices manually, or let the device configure trusted devices automatically. Aside from

dropping packets as a response to any violations, you can also configure ports to enter "port shutdown" and achieve a strict security guarantee. When a violation is registered on a port, the port will shut down and an administrator will receive a notification to perform a check.

MAC Sticky

Menu Path: Security > Network Security > Port Security - MAC Sticky

This page lets you configure MAC Sticky.

Note

This tab will only appear when Port Security Mode is set to MAC Sticky.

Limitations

You can create up to 1024 MAC Sticky entries.

MAC Sticky - Port Security Info

The screenshot shows the 'Port Security' configuration page with the 'MAC Sticky' tab selected. Below the tabs is a 'Port Security Info' section containing a table with the following data:

Port Security mode	Total Trust Hosts	The max. number of addresses in the system
MAC Sticky	0	1024

UI Setting	Description
Port Security mode	Shows the port security mode being used.
Total Trust Hosts	Shows the number of trusted hosts allowed to access the network.

UI Setting	Description
The max. number of address in the system	Show the maximum number of MAC addresses allowed to be learned or specified for port security.

About Traffic Storm Control

A traffic storm can happen when packets flood the network and cause excessive traffic, slowing down network performance. To counter this, Traffic Storm Control provides an efficient design to prevent the network from flooding caused by a broadcast, multicast, or unicast traffic storm on a physical network layer. Traffic Storm Control can handle packets from both ingress and egress data.

Traffic Storm Control

Menu Path: Security > Network Security > Traffic Storm Control

This page lets you configure traffic storm control for each port.

Traffic Storm Control					
	Port	Broadcast	Multicast	DLF	Threshold (fps)
	1	Enabled	Disabled	Disabled	12700
	2	Enabled	Disabled	Disabled	12700

About Access Control Lists

Access Control Lists (ACLs) help you control network traffic based on specific criteria.

Here's an overview of some different kinds of ACLs:

- **Security:** ACLs provide a means to control access to network resources based on specific criteria such as source or destination IP addresses, MAC addresses, protocols, or port numbers. By implementing ACLs, you can enforce security policies and restrict unauthorized access to sensitive resources.
- **Traffic Management:** ACLs allow you to manage network traffic by selectively permitting or denying certain types of traffic. This helps optimize network performance by prioritizing critical traffic and controlling bandwidth usage.
- **Compliance:** In many industries, organizations are required to comply with security regulations and standards that mandate access control measures. By enabling ACLs, you can implement and demonstrate compliance with these requirements and mitigate security risks.
- **Protection Against Attacks:** ACLs can help protect networks against various types of attacks by blocking malicious traffic before it reaches its intended destination.
- **Preventing Unauthorized Access:** By implementing ACLs, you can prevent unauthorized users or devices from accessing network resources, reducing the risk of data breaches and unauthorized activities.

Overall, enabling ACLs enhances network security, improves traffic management, helps ensure compliance with regulations, and protects against various threats and attacks.

Access Control Lists In Depth

In an Ethernet switch, Access Control Lists (ACLs) work by examining incoming or outgoing packets and making decisions based on predefined rules. Each access list is a filter. When a packet enters into or exits from a switch, ACL will compare the packet to the rules in the access lists, starting from the first rule. If a packet is rejected or accepted by the first rule, the switch will drop or pass this packet directly without checking the rest of the lower-priority rules.

Here's how it typically works:

1. **Packet Inspection:** When a packet arrives at a switch port, the switch inspects the packet headers, including source and destination MAC addresses, IP addresses, and port numbers.
2. **ACL Lookup:** The switch compares the packet's header information against the ACL rules configured on the switch. These rules define which types of traffic are allowed or denied based on specific criteria such as MAC addresses, IP addresses, protocols, or port numbers.
3. **Decision Making:** Based on the ACL rules, the switch decides whether to permit or deny the packet. If the packet matches an ACL rule that permits the traffic, it is forwarded according to the switch's normal forwarding behavior. If the packet matches an ACL rule that denies the traffic, it is either dropped or forwarded to a specified destination, depending on the ACL configuration.
4. **Logging and Statistics:** Some switches may also provide logging and statistical features for ACLs, allowing administrators to monitor and analyze network traffic and ACL rule matches.

Overall, ACLs in Ethernet switches provide a mechanism for controlling access to network resources based on specific criteria, helping to enforce security policies and manage network traffic.

Active Egress Port	Shows the active egress ports configured.
Index	Shows the index number for the ACL rule.
ACL Rule	Shows whether the ACL rule is enabled.
Rule Type	Shows the rule type.
Protocol	Shows the protocol used for the ACL rule.
Source	Shows the source IP address with its subnet mask.
Destination	Shows the destination IP address with its subnet mask.
DSCP	Shows the DSCP value specified to differentiate the prioritization of IP packets.
Optional Parameter	Shows the relevant parameters for the selected protocol.
Action	Shows whether the redirect action and DSCP remark are enabled. If enabled, shows their respective configuration settings.
Hit Count	Shows the hit count of the ACL rule.

ACL Table Status - MAC-index

If the selected ACL uses **MAC-index**, the following table will appear.

The screenshot shows the configuration for 'ACL Table of MAC-1'. It includes fields for Name (Test 2), Active Ingress Ports (1, 3), and Active Egress Ports (4, 5). Below this is a search bar and a table with the following columns: Index, ACL Rule, Rule Type, EtherType, Source, Destination, VLAN ID, CoS, Action, and Hit Count. The table contains one row with the following values: Index: 1, ACL Rule: Enabled, Rule Type: Permit, EtherType: Any, Source: Any, Destination: Any, VLAN ID: Any, CoS: Any, Action: None, Hit Count: 0.

Index	ACL Rule	Rule Type	EtherType	Source	Destination	VLAN ID	CoS	Action	Hit Count
1	Enabled	Permit	Any	Any	Any	Any	Any	None	0

UI Setting	Description
Name	Shows the name of the access list.

UI Setting	Description
Active Ingress Port	Shows the active ingress ports configured.
Active Egress Port	Shows the active egress ports configured.
Index	Shows the index number for the ACL rule.
ACL Rule	Shows whether the ACL rule is enabled.
Rule Type	Shows the rule type.
EtherType	Shows the EtherType used for the ACL rule.
Source	Shows the source MAC address with its mask.
Destination	Shows the destination MAC address with its mask.
VLAN ID	Shows the VLAN ID.
CoS	Shows the CoS value specified to differentiate the prioritization of packets.
Optional Parameter	Shows the relevant parameters for the selected EtherType.
Action	Shows whether the redirect action and CoS remark are enabled. If enabled, shows their respective configuration settings.
Hit Count	Shows the hit count of the ACL rule.

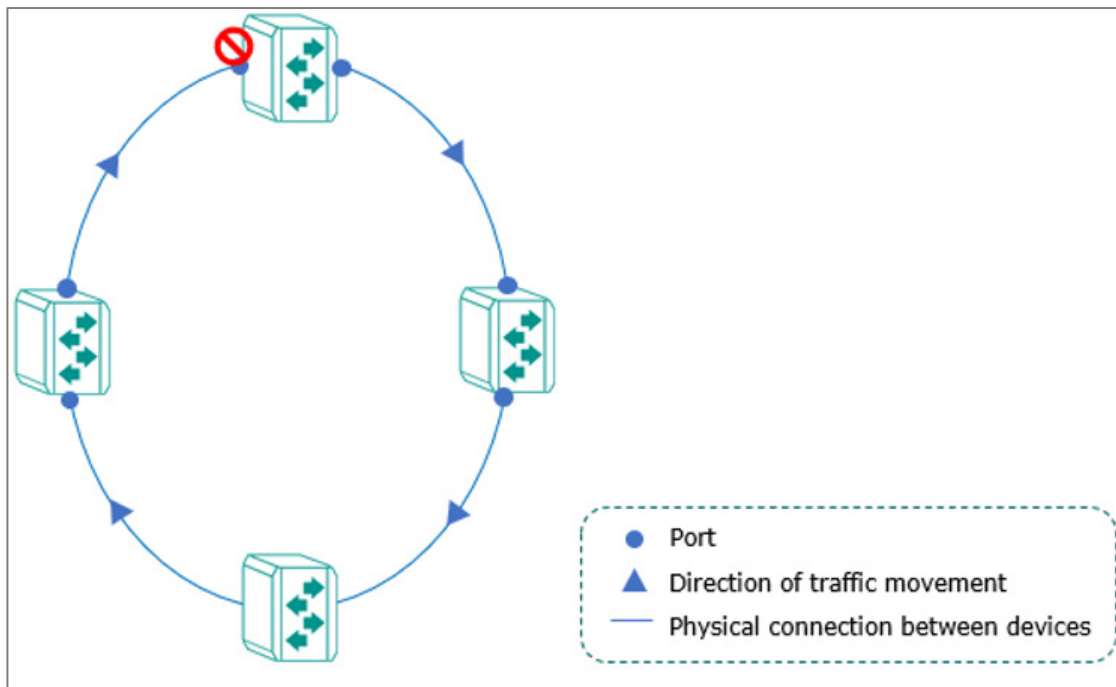

About Network Loop Protection

Network Loop Protection helps avoid network loops by disabling ports when looping is detected in the network topology. This is designed for devices that do not support redundant protocols, when redundant protocols are not configured, or if the redundant protocol fails.

Network Loop Protection In Depth

Network Loop Protection prevents looping by sending detection packets through the network topology to all ports. After receiving a packet, a port will check if the packet was sent by the device itself. If so, the receiving port will be disabled to prevent looping.

Network loop protection features cannot prevent ports from activating redundancy protocols—such as STP, RSTP, MSTP, Turbo Ring, Ring Coupling, Turbo Chain, Dual Homing, or Link Aggregation—from looping, as these ports do not process detection packets sent by the Network Loop Protection features.

Network Loop Protection

Menu Path: [Security](#) > [Network Security](#) > [Network Loop Protection](#)

Loop Status	Show the loop status of the port. <ul style="list-style-type: none">• Normal: The port is not looping.• Looping: The port is looping.
Port Status	Shows the port status of the specific port. <ul style="list-style-type: none">• Disabled: The port is disabled due to a port shutdown or detected loop.
Peer Port	Shows the port where the looping frames are from when detecting a loop.

About Binding Databases

A binding database acts as an allowlist for IP Source Guard and Dynamic ARP Inspection to help protect against unauthorized traffic.

Binding Databases In Depth

A binding database consists of dynamic entries and static entries.

- **Dynamic Entries**: Generated automatically after a DHCP client successfully obtains an IP while DHCP snooping is enabled. The entry will be released after exceeding the IP lease time or upon disabling DHCP snooping.

- **Static Entries:** User-generated/edited entry. The entry will be released only when a user deletes it.

Binding database entries consist of VLAN IDs, MAC addresses, ports, and IP addresses. This information forms an allowlist used by IP Source Guard to filter IP packets, and for Dynamic ARP Inspection to filter ARP packets. This helps prevent spoofing attacks such as man-in-the-middle and denial-of-service attacks.

Configuring Binding Database

Binding Database is the base for IP Source Guard and Dynamic ARP Inspection, there are two ways to populate Binding Database entries, including entries automatically created after enabling DHCP Snooping or manually entries created by users.

Before you begin:

- Determine which kind of Binding Database Entries to use: Static, or Dynamic. See above for guidelines to make this determination.

Configuring Dynamic Binding Database Entries

To configure a Dynamic Binding Database entry:

1. Go to **Security > Network Security > DHCP Snooping**.
2. Click DHCP Snooping and then select Enable, optionally specify a VLAN ID, and then click Apply.

3. Under Port Settings, click **Edit** (✎) to configure the corresponding port binding settings.
4. Configure the following:
 - **Status**
 - **Copy configurations to ports**
5. Click **Apply**

Results: The Binding Database entries will be created upon a successful DHCP transaction on DHCP Snooping-enabled Untrusted ports. You can view the binding database entries by going to **Security > Network Security > Binding Database > Binding Status**.

Configuring Static Binding Database Entries

To configure a Static Binding Database Entry:

1. Go to **Security > Network Security > Binding Database.> Binding Setting**.
2. Click (Add), and then specify all of the following:
 - **VLAN ID**
 - **MAC Address**
 - **Port**
 - **IP Address**
3. Click **Create** to add the entry to the database.

Results: The Binding Database entries will be created upon a successful DHCP transaction on DHCP Snooping-enabled Untrusted ports. You can view the binding database entries by going to **Security > Network Security > Binding Database > Binding Status**.

Binding Database

Menu Path: [Security > Network Security > Binding Database](#)

This page lets you view and manage the binding database, which can be used for an allowlist for IP Source Guard or Dynamic ARP Inspection.

This page includes these tabs:

- Binding Settings
- Binding Status

🔒 Limitations

You can create up to 32 binding database entries, including dynamic and static entries. Entries will stop being generated or being user-addable when this limit is reached. More entries can only be added when existing entries are released, bringing the total number below 32.

Binding Settings

Menu Path: Security > Network Security > Binding Database - Binding Settings

This page lets you manage the static entries you want to use for an allowlist.

Binding Settings List

Binding Database

Binding Settings | Binding Status

+

<input type="checkbox"/>	VLAN ID	MAC Address	Port	IP Address

MAC Address	Shows the MAC address for the static entry.
Port	Shows the port for the static entry.
IP Address	Shows the IP address for the static entry.

Create a Binding Database Static Entry

Menu Path: Security > Network Security > Binding Database - Binding Settings

Clicking the **Add (+)** icon on the **Security > Network Security > Binding Database - Binding Settings** page will open this dialog box. This dialog lets you a new static entry to be an allowlist base for IP Source Guard or Dynamic ARP Inspection.

Click **CREATE** to save your changes and add the new entry.

Create a Binding Database Static Entry

VLAN ID * MAC Address *

Port *

IP Address *

UI Setting	Description	Valid Range	Default Value
VLAN ID	Specify the VLAN ID to allowlist for IP Source Guard or Dynamic ARP Inspection.	1 to 4094	N/A
MAC Address	Specify the MAC address to allowlist for IP Source Guard or Dynamic ARP Inspection.	Valid MAC address	N/A
Port	Specify the port to allowlist for IP Source Guard or Dynamic ARP Inspection.	Drop-down list of subnet masks	N/A
IP Address	Specify the IP address to allowlist for IP Source Guard or Dynamic ARP Inspection.	Valid IP address	N/A

Binding Status

Menu Path: Security > Network Security > Binding Database - Binding Status

This page lets you view the current binding database entries of your device.

Binding Status List

Binding Database

Binding Settings **Binding Status**

Dynamic binding is learning from DHCP snooping.
The binding status will not be updated if the VLAN ID and MAC address combination of the static entry already exists.

Type	VLAN ID	MAC Address	Port	IP Address	Lease Time	Active
Max. 32						

UI Setting	Description
VLAN ID	Shows the VLAN ID for a successful DHCP packet transaction on an untrusted port, or the specified VLAN ID for a user-created static entry.
MAC Address	Shows the MAC address for a successful DHCP packet transaction on an untrusted port, or the specified MAC address for a user-created static entry.
Port	Shows the untrusted port for a successful DHCP packet transaction, or the specified port for a user-created static entry.
IP Address	Shows the IP address for a successful DHCP packet transaction on an untrusted port, or the specified IP address for a user-created static entry.
Lease Time	Shows the lease time for the entry to be active. The lease time is infinite for user-created static entries.
Active	Shows whether the entry is active for use with IP Source Guard, Dynamic ARP Inspection, or both.

About DHCP Snooping

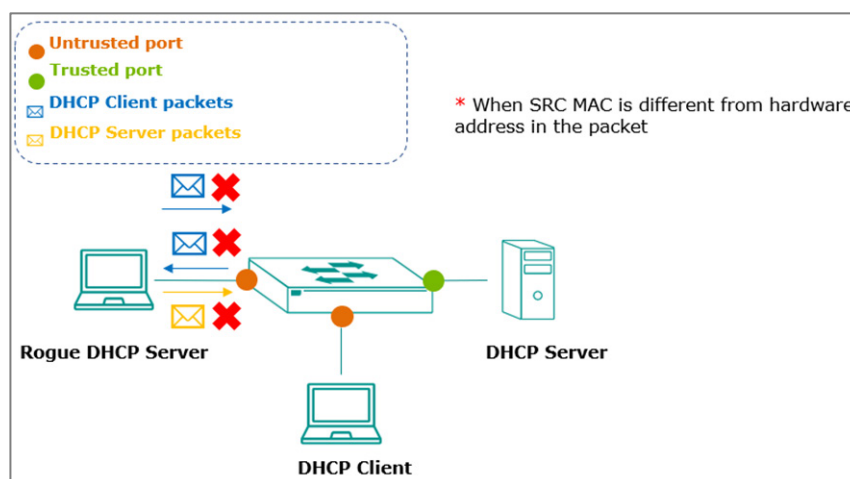

DHCP Snooping is a VLAN-specific security feature for DHCP operations. You can configure untrusted hosts and trusted DHCP servers for corresponding ports on your device, and then the feature will act like a firewall to validate DHCP messages received from untrusted sources and filter out invalid messages to exclude rogue DHCP servers and remove malicious DHCP traffic. This helps guarantee that clients obtain a legal address from the DHCP server you designate.

Enabling DHCP snooping will also set up a binding database, which will act as an allowlist for IP Source Guard and Dynamic ARP Inspection.

DHCP Snooping In Depth

By configuring the designated ports connected to DHCP server ports as trusted ports, and ports connected to clients/hosts as untrusted ports:

- Trusted ports will allow all DHCP packets.
- Untrusted ports will handle DHCP packets as follows:
 - a. Pass ingress DHCP client packets and egress DHCP server packets to complete normal DHCP transactions.
 - b. Drop egress DHCP client packets and ingress DHCP server packets to avoid rogue DHCP server attacks.
 - c. Drop DHCP client packets with a different source MAC address and hardware address to avoid malicious DHCP client attacks.

Successful DHCP transactions with DHCP snooping enabled will create and update the binding database. The binding database contains VLAN IDs, MAC addresses, untrusted ports of DHCP clients, and IP addresses. The binding database can also be used for other security functions such as IP Source Guard and Dynamic ARP Inspection.

DHCP Snooping

Menu Path: Security > Network Security > DHCP Snooping

This page lets you manage DHCP Snooping for your device.

DHCP Snooping Settings

UI Setting	Description	Valid Range	Default Value
DHCP Snooping	Enable or disable DHCP snooping.	Enabled / Disabled	Disabled
VLAN ID	Specify the VLAN IDs to use for DHCP snooping. You can enter multiple VLAN IDs by separating them with commas or by using ranges (e.g., 2, 4-8, 10-13).	1 to 4094	N/A

DHCP Snooping - Port Settings

Port Settings		
	Port	Status
	1	Untrusted
	2	Untrusted
	3	Untrusted
	4	Untrusted

UI Setting	Description
Port	Shows the port number the entry is for.
Status	Shows whether the port is trusted or untrusted.

DHCP Snooping - Edit Port Settings

Menu Path: Security > Network Security > DHCP Snooping

Clicking the **Edit** () icon for a port on the **Security > Network Security > DHCP Snooping** page will open this dialog box. This dialog lets you configure the port as trusted or untrusted for DHCP snooping.

Click **APPLY** to save your changes.

Edit Port 1 Settings

Status	Specify the port as untrusted or trusted.	Untrusted / Trusted	Untrusted
Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

About IP Source Guard

IP Source Guard (IPSG) is an IP data packet filtering security feature that works on Layer 2 interfaces. It works together with DHCP Snooping and the Binding Database to filter IP data packets to defend against attacks such as denial-of-service (DoS) that are caused by forging/spoofing source IP addresses.

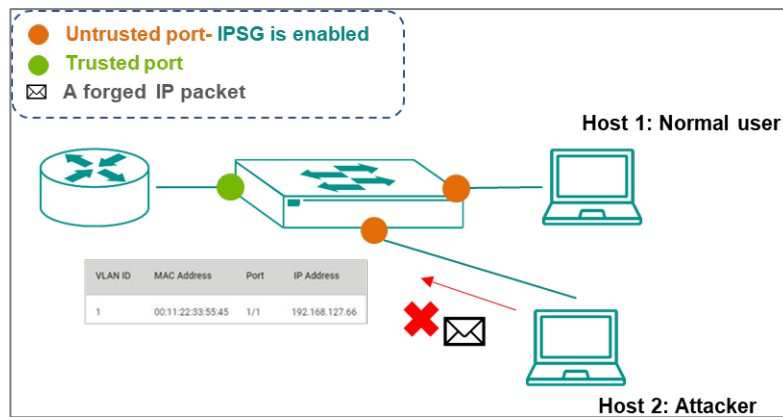

IP Source Guard In Depth

IPSG checks all traffic to make sure its host IP address, MAC address, VLAN, and port match a valid entry in the binding database. If the host does not match a valid entry in the binding database, the traffic will not be forwarded.

Note

IP Source Guard (IPSG) works with DHCP snooping, so DHCP snooping must be enabled to create binding database entries before enabling IPSG

IPSG can only be used on ports specified as "untrusted" for DHCP snooping.

IP Source Guard

Menu Path: Security > Network Security > IP Source Guard

This page lets you enable or disable IP Source Guard for each port.

IP Source Guard List

IP Source Guard		
	Port	Status
	1	Disabled
	2	Disabled
	3	Disabled
	4	Disabled

UI Setting	Description
Port	Shows the port number the entry is for.
Status	Shows whether IP Source Guard is enabled for the port.
	 Note IP Source Guard can only be enabled on ports specified as untrusted in DHCP snooping.

IP Source Guard - Edit Port Settings

Menu Path: [Security](#) > [Network Security](#) > [IP Source Guard](#)

Clicking the **Edit** () icon for a port on the **Security > Network Security > IP Source Guard** page will open this dialog box. This dialog lets you enable or disable IP Source Guard for the port.

Click **APPLY** to save your changes.

Edit Port 1 Settings

Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

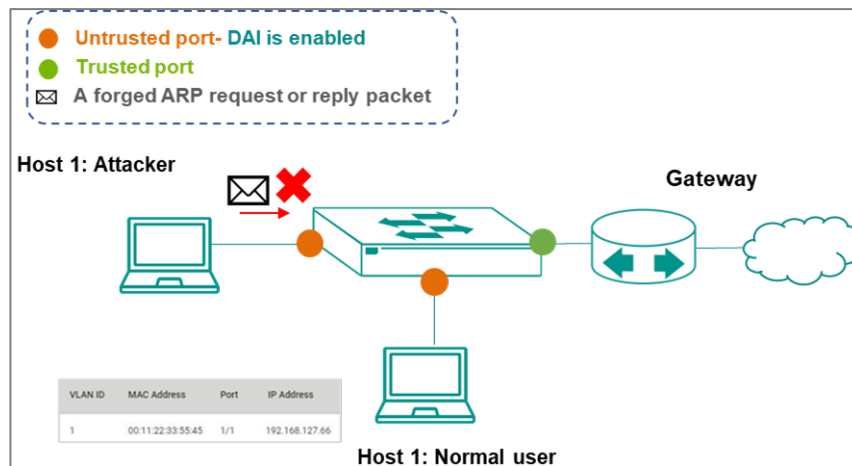

About Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) is an ARP packet filtering security feature that works on Layer 2 interfaces. It works together with DHCP snooping and the binding database to help defend against attacks such as man-in-the-middle or denial-of-service (DoS) attacks caused by ARP packet spoofing (also known as ARP poisoning or ARP cache poisoning).

Dynamic ARP Inspection In Depth

Dynamic ARP Inspection (DAI) works with DHCP Snooping. Users must enable DHCP snooping to create Binding Database entries before enabling DAI, and DAI can only be used on ports specified as untrusted DHCP Snooping.

DAI inspects each ARP packet sent from a host attached to an untrusted port on the switch. The IP address, MAC address, VLAN, and port associated with the host are checked against entries stored in the Binding Database. If the host information does not match a valid entry in the Binding Database, the ARP packet will not be forwarded.

Dynamic ARP Inspection

Menu Path: Security > Network Security > Dynamic ARP Inspection

This page lets you enable or disable Dynamic ARP Inspection for each port.

Dynamic ARP Inspection List

Dynamic ARP Inspection		
	Port	Status
	1	Disabled

Authentication

Menu Path: Security > Authentication

This section lets you manage the authentication features of your device.

This section includes these pages:

- Login Authentication
- RADIUS
- TACACS+

About Login Authentication

Your device can authenticate user logins to protect against unauthorized access to your device.

How Login Authentication Works

Your device has three different methods of authenticating user logins:

- TACACS+ (Terminal Access Controller Access-Control System Plus)
- RADIUS (Remote Authentication Dial In User Service)
- Local database

TACACS+ and RADIUS are centralized “AAA” (Authentication, Authorization, and Accounting) systems for connecting to network services. The fundamental purpose of these is to provide an efficient and secure mechanism for user account management.

You can use different combinations of these authentication methods:

1. **TACACS+, Local:** Check the TACACS+ database first. If checking the TACACS+ database fails, then check the local database.
2. **RADIUS, Local:** Check the RADIUS database first. If checking the RADIUS database fails, then check the local database.
3. **TACACS+:** Only check the TACACS+ database.
4. **RADIUS:** Only check the RADIUS database.
5. **Local:** Only check the local database.

Login Authentication

Menu Path: Security > Authentication > Login Authentication

This page lets you select the login authentication protocol for your device.

Login Authentication Settings

 **Note**

The account privilege level will be granted based on the service type setting for the user for RADIUS authentication, and the privilege level for the user for TACACS+ authentication.

RADIUS Service Type

- 6: Administrator
- 3: Supervisor
- All other values (1, 2, 4, 5, 7, 8, 9, 10, 11): User

TACACS+ Privilege Level

- 15: Administrator
- 12: Supervisor
- 1: User

Login Authentication

Authentication Protocol

UI Setting	Description	Valid Range	Default Value
Authentication Protocol	<p>Select the login authentication protocol to use for your device.</p> <ul style="list-style-type: none"> • Local: Only the local database will be checked for login authentication. • RADIUS: Only the RADIUS database will be checked for login authentication. • TACACS+: Only the TACACS+ database will be checked for login authentication. • RADIUS, Local: The RADIUS database will be checked first for login authentication. If checking the RADIUS database fails, then the local database will be checked. • TACACS+, Local: The TACACS+ database will be checked first for login authentication. If checking the TACACS+ database fails, then the local database will be checked. 	Local / RADIUS / TACACS+ / RADIUS, Local / TACACS+, Local	Local

RADIUS

RADIUS, or Remote Authentication Dial-In User Service, acts like a central security checkpoint for your network. It verifies the identities of users and devices trying to connect, ensuring only authorized ones gain access. Imagine it as a doorman for your switch – RADIUS checks credentials and grants permission to enter the network, enhancing overall security. This centralized approach simplifies user management and eliminates the need for individual security configurations on each device. RADIUS is particularly useful for businesses with many users, devices, or remote access needs.

RADIUS

Menu Path: Security > Authentication > RADIUS

This page lets you configure the RADIUS settings for your device.

RADIUS Settings

UI Setting	Description	Valid Range	Default Value
Retry (sec.)	Specify how many times to try reconnecting to the RADIUS server.	0 to 5	1

TACACS+

Terminal Access Controller Access Control System Plus (TACACS+) helps provide network access control by verifying users, authorizing their actions (like read, write, or configure), and keeping a detailed log of activity. This granular control allows you to restrict what users can do on specific network devices, ensuring security and compliance. TACACS+ is especially beneficial for network administrators who need to manage user access privileges and track activity across multiple devices.

TACACS+

Menu Path: [Security](#) > [Authentication](#) > [TACACS+ Server](#)

This page lets you configure the TACACS+ settings for your device.

Note

The TACACS+ service will be operated using the 1st server specified. If it fails, it will run on the 2nd server specified.

Note

Users created with the TACACS+ server will be granted Admin privileges.

TACACS+ Settings

Note

After leaving this page or refreshing, the Share Key fields will automatically be cleared to enhance security.

- Module Information

About Resource Utilization

Resource Utilization provides a set of monitoring tools to give you insights into the switch's current and historical resource usage.

These tools typically include current usage and usage over time for:

- **CPU Utilization**

- **Memory Utilization**
- **Power Utilization**

Note

Power utilization monitoring is only supported for MDS devices.

Resource Utilization

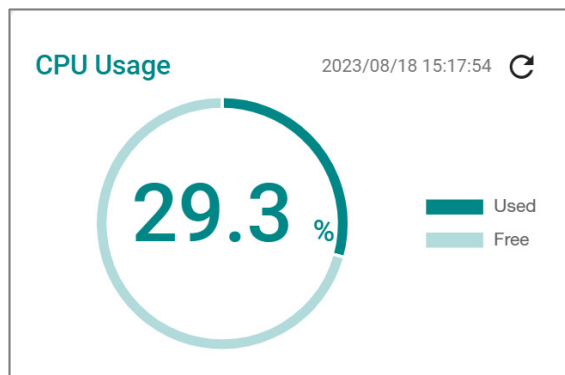

Menu Path: [Diagnostics](#) > [System Status](#) > [Resource Utilization](#)

This page lets you monitor current and historical system resource utilization.

CPU Usage

This display shows the device's CPU usage.

Click the **Refresh** (🔄) icon to refresh the graph.

UI Setting	Description
CPU Usage	Displays the current utilization of the CPU.

CPU Usage History (%)

The device's CPU usage will be shown as a percentage over time.

Click the **Refresh** (🔄) icon to manually add the current value to the chart.

Click the icon on the top-right corner of the widget to select which data to display.

UI Setting	Description
CPU Usage History	Displays the device's CPU usage over time.

Memory Usage

This display shows the device's memory usage.

Click the **Refresh** (🔄) icon to refresh the graph.

UI Setting	Description
Memory Usage	Displays the memory utilization status.

Memory Usage History

The device's memory usage will be shown as a percentage over time.

Click the **Refresh** (🔄) icon to manually add the current value to the chart.

UI Setting	Description
Memory Usage History	Displays the device's memory usage over time.

Power Consumption

This display shows the device's current power consumption in watts.

Click the **Refresh** () icon to refresh the value.

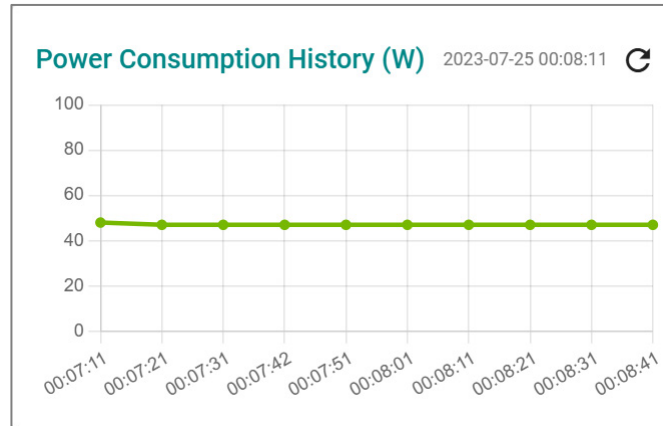

UI Setting	Description
Power Consumption	Displays the current power consumption of the device in watts.

Power Consumption History

This shows the device's power consumption over time.

Click the **Refresh** () icon to manually add the current value to the chart.

UI Setting	Description
Power History	Displays the device's power consumption in watts over time.

About Fiber Check

Optical fiber is commonly used for long-distance data transmission, so it is very costly to troubleshoot fiber cables and fiber transceivers at remote sites when issues occur. This device provides Fiber Check features to help check and diagnose the link status of fiber connectors—including Moxa’s SFP and fixed type (multi-mode SC/ST and single-mode SC) connectors—by displaying the optical parameters and corresponding thresholds. This makes it easier to remotely determine if the modules are working properly, and lets you send notifications when a threshold has been exceeded, greatly facilitating the troubleshooting process and reducing the need for onsite checks.

Fiber Check In Depth

The Fiber Check feature displays the running status and corresponding thresholds for your device's fiber ports.

The running status shows the current wavelength, temperature, voltage, Tx power, and Rx power for the port. It also shows the corresponding high and low thresholds for temperature, voltage, Tx power, and Rx power for the port, based on its module. You can choose to use the default thresholds for a port by using Auto mode, or define the thresholds manually by using the User Define mode. Refer to [Fiber Check Threshold Values for Auto Mode](#) for more information on the default thresholds.

When a threshold is exceeded, a **Fiber Check warning** event will be triggered, which can be used to send notifications to a trap server, email, or relay, or add an event log to the syslog. Refer to [Event Notifications - Port](#) for more information.

 **Note**

This feature is only designed for Moxa's SFP and fixed type (multi-mode SC/ST and single-mode SC) fiber modules.

Fiber Check

Menu Path: [Diagnostics](#) > [System Status](#) > [Fiber Check](#)

This page lets you diagnose the link status of the device's fiber connectors, including SFP and fixed type (multi-mode SC/ST and single-mode SC) connectors. It lets you monitor the temperature, TX/RX power, and other parameters on fiber ports to determine if the ports are working properly.

You can enable trap, email warning, and/or relay warning functions to receive an alarm or relay if one of the fiber ports exceeds the threshold for that port. Refer to [Diagnostics > Event Logs and Notifications](#) for more information.

This page includes these tabs:

- Status
- Threshold Settings

Fiber Check - Status

Menu Path: [Diagnostics](#) > [System Status](#) > [Fiber Check - Status](#)

This page lets you view the current status of your device's fiber ports.

Fiber Check Port List

Port	Model Name	Serial Number	Wavelength (nm)	Voltage (V)	Temperature (Threshold) (°C)	Tx Power (Threshold Low/High) (dBm)	Rx Power (Threshold Low/High) (dBm)
1/1	SFP-1GLXLC-T	A000000009	1310	3.30	41.50 (120.00)	-6.78 (-9.00/-3.00)	--- (-21.00/-3.00)
1/2	SFP-1GLXLC	K000000005	1310	3.31	45.81 (100.00)	-5.57 (-9.00/-3.00)	--- (-21.00/-3.00)
1/3	--	--	--	--	--	--	--

UI Setting	Description
Port	Shows the port the entry is for.
Model Name	Shows the model name of the port.
Serial Number	Shows the serial number of the port.
Wavelength	Shows the wavelength in nm of the port.
Voltage	Shows the voltage in V of the port.
Temperature Threshold	Shows the current temperature of the port, and the low and high temperature thresholds in parentheses (). You can change between C and F temperatures by using the buttons at the top of the table.
Tx Power (Threshold Low/High)	Shows the current Tx power in dBm of the port, and the low and high thresholds for Tx power in parentheses ().
Rx Power (Threshold Low/High)	Shows the current Rx power in dBm of the port, and the low and high thresholds for Rx power in parentheses ().

Fiber Check - Threshold Settings

Menu Path: [Diagnostics](#) > [System Status](#) > [Fiber Check - Threshold Settings](#)

This page lets you configure fiber check threshold parameters for sending event notifications.

Fiber Check Threshold Port List

	Port	Mode	Temperature Threshold (°C)	Tx Power Threshold Low (dBm)	Tx Power Threshold High (dBm)	Rx Power Threshold Low (dBm)	Rx Power Threshold High (dBm)
	1/1	Auto	---	---	---	---	---
	1/2	Auto	---	---	---	---	---

- [ARP Table](#)

About Network Statistics

Network Statistics provides monitoring tools that give you a real-time view of traffic flowing through the device.

This information typically includes:

- **Packet Counter:** The number of data packets being transmitted and received within a specific period of time, providing a crucial metric for assessing the activity and load on a network's infrastructure.
- **Bandwidth Utilization:** The percentage of the total bandwidth currently being used for data transmission.

Network Statistics

Menu Path: Diagnostics > Network Status > Network Statistics

This page lets you see the real-time packet and bandwidth status for your device.

Network Status Display

You can switch between **Packet Counter** and **Bandwidth Utilization** views by clicking on the **Display Settings (**

) icon on the top-right.

- **Packet Counter:** This view shows how many packets are being handled over time. This view updates every 5 seconds.
- **Bandwidth Utilization:** This view shows bandwidth utilization over time. This view updates every 3 seconds.

UI Setting	Description
Refresh ()	Updates statistics immediately without waiting for the refresh interval.
Reset the Statistics Graph () (For Packet Counter display only)	Clears the display and resets display settings back to defaults.

UI Setting	Description
Display Settings (☰))	Opens Display Settings , which allows you to switch between Packet Counter and Bandwidth Usage view, and add lines based on user-defined criteria.
Compare Data (📊) (For Packet Counter display only)	Compare data by selecting a benchmark line and time and a comparison line and time.

About LLDP

Link Layer Discovery Protocol (LLDP) is an OSI Layer 2 protocol defined by IEEE 802.11AB. LLDP standardizes the self-identification advertisement method, and allows each networking device to periodically send its system and configuration information to its neighbors. Because of this, all LLDP devices are kept informed of each other's status and configurations. With SNMP, this information can be transferred to Moxa's MXview One for auto-topology and network visualization.

From the device's web interface, you can enable or disable LLDP, and set the LLDP transmit interval. In addition, you can view each switch's neighbor list, which is reported by its network neighbors. Most importantly, enabling the LLDP function allows Moxa's MXview One to automatically display the network's topology and system setup details, such as VLAN and Trunking for the entire network.

LLDP

Menu Path: [Diagnostics](#) > [Network Status](#) > [LLDP](#)

UI Setting	Description	Valid Range	Default Value
LLDP	Enable or disable Link Layer Discovery Protocol (LLDP).	Enabled / Disabled	Enabled
LLDP Version	Shows the LLDP version.	v1(2005)	v1(2005)
Transmit Interval	Specify how long in seconds the interval will be in between sending LLDP messages.	5 to 32768	30
Notification Interval	Specify how long in seconds the interval will be in between sending notifications.	5 to 3600	5

UI Setting	Description	Valid Range	Default Value
Tx Delay	Specify how long in seconds the interval will be in between successive LLDP frame transmissions initiated by changes.	1 to 8192	2
Reinitialization Delay (Only in Advanced Mode)	Specify how long in seconds the delay will be before reinitializing an LLDP packet transmission.	1 to 10	2
Holdtime Multiplier (Only in Advanced Mode)	Specify how long in seconds the receiving device will hold an LLDP packet before discarding it.	2 to 10	4
Chassis ID Subtype	Specify the Chassis ID subtype of the device.	Chassis-Component / If-Alias / Port-Component / MAC-Address / Network-Address / If-Name / Local	MAC-Address
Chassis ID (If Chassis ID Subtype is Chassis-Component, Port-Component, or Local)	Specify the Chassis ID. <div style="border: 1px solid gray; background-color: #f0f0f0; padding: 5px;"> <p>Note</p> <p>The MAC address of the default VLAN is often used for the Chassis ID.</p> </div>	1 to 255 characters	N/A

LLDP Port List

Port	Port Status
1/1	Tx and Rx
1/2	Tx and Rx
1/3	Tx and Rx
1/4	Tx and Rx
2/1	Tx and Rx
2/2	Tx and Rx

UI Setting	Description
Port	Shows the port number the entry is for.
Port Status	Show the status of what data is being transmitted for the port.

LLDP - Edit Port Settings

Menu Path: Diagnostics > Network Status > LLDP - Settings

Clicking the **Edit** (✎) icon for a port on the **Diagnostics > Network Status > LLDP - Settings** page will open this dialog box. This dialog lets you configure the LLDP settings for the port.

Click **APPLY** to save your changes.

UI Setting	Description	Valid Range	Default Value
Port Status	Specify the port status for transmitting data.	Tx and Rx / Tx Only / Rx Only	Tx and Rx
Subtype	Specify the Chassis ID subtype for the port.	Chassis-Component / If-Alias / Port-Component / MAC-Address / Network-Address / If-Name / Local	If-Alias
Basic Transmit TLVs	Select the basic information to use for the TLV. You can select multiple options.	Port Description / System Name / System Description	Port Description, System Name
802.1 Transmit TLVs	Select the 802.1 information to use for the TLV. You can select multiple options.	Port VLAN ID / VLAN Name	N/A
802.3 Transmit TLVs	Select the 802.3 information to use for the TLV. You can select multiple options.	Link Aggregation Statistics / Maximum Frame Size	N/A

UI Setting	Description	Valid Range	Default Value
Copy configurations to ports	Select the ports you want to copy this configuration to.	Drop-down list of ports	N/A

LLDP - Status

Menu Path: Diagnostics > Network Status > LLDP - Status

This page lets you see the status of LLDP on your device.

Local Information

Local Information
LLDP Enabled
LLDP Version v1(2005)
Chassis ID Subtype MAC-Address
Chassis ID 00:90:e8:af:4b:17
System Capability Bridge, Router
Interface ID / Management Address 130 / 192.168.127.253

UI Setting	Description
LLDP	Shows whether LLDP is enabled.
LLDP Version	Shows the LLDP version.
Chassis ID Subtype	Shows the chassis ID subtype.
Chassis ID	Shows the chassis ID.
System Capacity	Shows the system capacity.
Interface ID / Management Address	Shows the interface ID and the management IP address.

Local Timer

Local Timer
Transmit Interval
30 (sec.)
Notification Interval
5 (sec.)
Tx Delay
2 (sec.)
Reinitialization Delay
2 (sec.)
Holdtime Multiplier
4 (times)

UI Setting	Description
Transmit Interval	Shows the interval between regular LLDP packet transmissions.
Notification Interval	Shows the interval between sending notifications.
Tx Delay	Shows the delay period between successive LLDP frame transmissions initiated by changes.
Reinitialization Delay	Shows the delay an LLDP port waits before reinitializing an LLDP packet transmission.
Holdtime Multiplier	Shows the amount of time that the receiving device will hold an LLDP packet before discarding it.

Remote Table Statistics

Remote Table Statistics

Last Change Time (ms)
1499300

Inserts

menu reference LLDP - Neighbor Status

LLDP - Neighbor Status

Menu Path: [Diagnostics](#) > [Network Status](#) > [LLDP - Neighbor Status](#)

This page lets you see the neighbor status of LLDP.

Neighbor Status

Local Port	System Capability	Neighbor Port ID	Neighbor Chassis ID	Port Description	System Name	Hold Time
3/3	---	---	---	---	---	---
3/4	Router	2	00:90:e8:00:00:05	100TX	NAT Router	---
3/5	---	---	---	---	---	---
3/6	---	---	---	---	---	---
3/7	---	---	---	---	---	---
3/8	Router	5	00:90:e8:a9:ed:2b	100TX	Firewall/ETBN Router 05518	---
4/1	---	---	---	---	---	---

UI Setting	Description
Local Port	Shows the number of the port connected to the neighbor.
System Capability	Shows the system capability of the neighbor.
Neighbor Port ID	Shows the neighbor's port ID for the interface this device is connected to.
Neighbor Chassis ID	Shows the unique ID (typically the MAC address) used to identify the neighbor device.
Port Description	Shows the neighbor's port description for the interface this device is connected to.
System Name	Shows the hostname of the neighbor device.
Hold Time	Shows the amount of time that the receiving device will hold an LLDP packet before discarding it.

About ARP Tables

The **ARP Table (Address Resolution Protocol Table)** is a database maintained by Ethernet switches. It acts like a translator that maps Media Access Control (MAC) addresses to their corresponding IP addresses. Network devices communicate using MAC addresses, which are unique hardware identifiers. However, routing between devices often relies on IP addresses, so ARP tables are used to bridge this gap.

ARP Table

Menu Path: Diagnostics > Network Status > ARP Table

This page lets you see the device's Address Resolution Protocol (ARP) table.

⚙ Limitations

The ARP table can show up to 3000 entries.

ARP Table

Index	IP Address	MAC Address	Interface
1	192.168.127.2	00:b5:6d:00:ea:e2	vlan1
2	192.168.127.254	00:90:e8:a9:ed:2b	vlan1

Max. 3000 Items per page: 50 1 - 2 of 2 << < > >>

UI Setting	Description
Index	Shows the index of the device entry.
IP Address	Shows the IP address used for the device.
MAC Address	Shows the MAC address of the device.

UI Setting	Description
Interface	Shows the interface the device is connecting through.

Tools

Menu Path: [Diagnostics > Tools](#)

This page lets you use various tools to help troubleshoot network issues.

This page includes these tabs:

- Port Mirroring
- Ping

About Port Mirroring

Port Mirroring is used to monitor data being transmitted through specific ports. This is done by setting up mirror ports to receive the same data being transmitted to, from, or both to and from the ports being monitored. Using mirror ports allows network administrators to sniff the observed ports to keep tabs on network activity.

Port Mirroring In Depth

There are two ways to use Port Mirroring on this device:

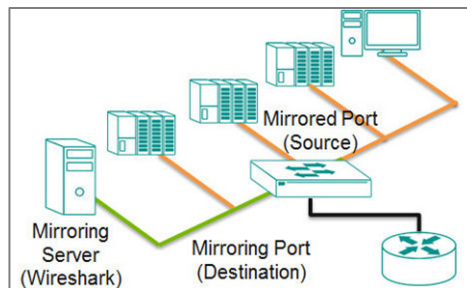

- **SPAN (Switched Port Analyzer):** Mirrors data from monitored ports to multiple terminal ports on the same switch.
- **RSPAN (Remote Switched Port Analyzer):** Mirrors data from monitored ports on one switch to multiple terminal ports on other switches.

SPAN

SPAN can be configured to copy packets from various ports to a single port or multiple ports, so that users can check if there are problems occurring in these ports.

For example, the following figure demonstrates how packets transmitted through the four mirrored ports (marked in orange) are copied (mirrored) to a single mirroring port (marked in green). These packets will be sent to a monitoring computer where software

is used to check for issues with the packets. This is useful for troubleshooting or monitoring network data transmissions for debugging or security purposes.

Ingress, egress, or both ingress and egress traffic can be mirrored one or more destination ports.

If you want to mirror traffic to multiple destination ports, than a reflect port needs to be assigned and the destination ports need to be in the same VLAN as the reflect port.

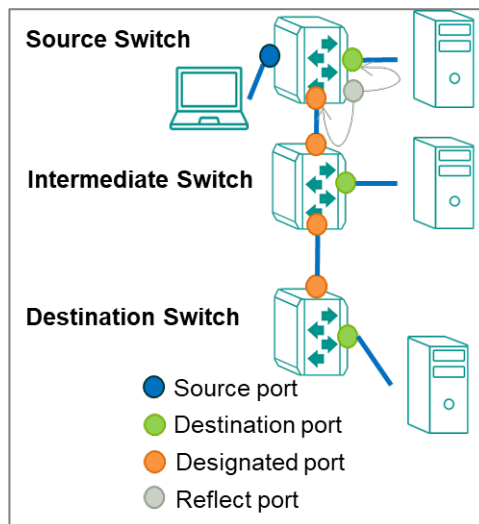

RSPAN

RSPAN can be configured to copy packets from one or more ports from one or more source switches through intermediate switches to one or more ports on destination switches. The PC or monitoring server can be connected to destination ports on the destination switch to receive a copy of the original traffic being monitored. For example, the following figure demonstrates how packets transmitted to a source port (marked in blue) are copied (mirrored) through an intermediate switch to one or more destination ports (marked in green). Source traffic can be copied through multiple intermediate switches to single or multiple destination switches.

Ingress, egress, or both ingress and egress traffic of the source port(s) can be mirrored to one or more destination ports on destination switches.

If you want to mirror traffic to destination ports on the source switch, a reflect port needs to be assigned. Destination ports in source switch, intermediate switch(es), and destination switch(es) need to be in the same VLAN as the reflect port.

- You can set source ports to be from one or more RSPAN source switches. If one of the destination ports is on a source switch, a reflect port needs to be assigned.
- You can configure an RSPAN VLAN for monitored traffic to be labeled with a RSPAN VLAN tag and send monitored traffic to an RSPAN destination switch via trunk ports.
- You can configure ports to join an RSPAN VLAN, these ports will be destination ports to receive monitored traffic.

- You can connect a monitoring computer to a destination port to receive monitoring traffic for software analysis or diagnostics.

Port Mirroring

Menu Path: Diagnostics > Tools > Port Mirroring

This page lets you configure port mirroring for your device.

This page includes these tabs:

- General
- SPAN
- RSPAN

Port Mirroring - General

Menu Path: Diagnostics > Tools > Port Mirroring - General

This page lets you enable or disable port mirroring for your device.

The screenshot shows the 'Port Mirroring' configuration page with three tabs: 'General', 'SPAN', and 'RSPAN'. The 'General' tab is active. Under the 'Port Mirroring *' label, there is a dropdown menu currently showing 'Enabled'. Below the dropdown is a green 'APPLY' button.

UI Setting	Description	Valid Range	Default Value
Port Mirroring	Enable or disable port mirroring to facilitate the creation of SPAN or RSPAN sessions.	Enabled / Disabled	Enabled

SPAN

Menu Path: Diagnostics > Tools > Port Mirroring - SPAN

This page lets you view and configure your device's SPAN settings.

🔒 Limitations

You can create up to 5 SPAN entries.

UI Setting Description

Session ID Shows the session ID the entry is for.

📌 Note

SPAN and RSPAN share 7 sessions, SPAN uses 1 to 5, and RSPAN uses 6 and 7.

Reflect Port Mode Shows whether Reflect Port Mode is enabled.

Tx Source Port(s) Shows the Tx source ports for the session.

Rx Source Port(s) Shows the Rx source ports for the session.

Destination Port Shows the destination port for the session.

Reflect Port Shows the reflect port for the session.

Creating a SPAN Session

Menu Path: [Diagnostics](#) > [Tools](#) > [Port Mirroring - SPAN](#)

Clicking the **Add (🛠️)** icon on the **Diagnosis > Port Mirroring - SPAN** page will open this dialog box. This dialog lets you create a SPAN session.

Click **CREATE** to save your changes and add the new session.

Create Session

Session ID * ▼

Ping

Ping lets you use the ping command through the device for a simple, but powerful tool for troubleshooting network problems. The unique feature of this is that even though the

ping command is entered in your browser window, the actual ping command will be sent from the Moxa device itself.

Ping

Menu Path: [Diagnostics](#) > [Tools](#) > [Ping](#)

This page lets you use the ping function, which is useful for troubleshooting network problems.

UI Setting	Description	Valid Range	Default Value
IP Address/Domain Name	Specify the IP address or domain name you want to ping, then click the PING button. The ping result will be displayed below.	Valid IP address or domain name up to 50 characters	N/A

Event Logs and Notifications

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#)

This section lets you set up and view your device's event logs and notifications.

This section includes these pages:

- Event Logs
- Event Notifications
- Syslog
- SNMP Trap/Inform

- Email Settings
- Relay Alarm

About Event Logs

Event logs automatically record important events that happen on the network connected to a switch. They are useful when troubleshooting network issues.

These events can include:

- **Changes in connection status:** This could be a cable being plugged in or unplugged, a device joining or leaving the network, or a port going up or down.
- **Errors:** The switch might detect issues like data corruption, excessive traffic, or problems with specific ports.
- **Security events:** Some switches can log attempts to access the switch itself or suspicious activity on the network.

Event Logs

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#) > [Event Logs](#)

This page lets you browse and export your device's various event logs.

This page includes these tabs:

- Event Logs
- Oversize Action
- Backup

Event Logs - Event Logs

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#) > [Event Logs - Event Logs](#)

This page lets you view your device's event logs.

🔒 Limitations

The system log can record up to 10000 events.

Actions

- Click the **Refresh icon** (🔄) to refresh the logs.
- Click the **Clear System Log icon** (🗑️) to delete all logs.
- Click the **Export icon** (📄) to export all logs to a file.

UI Setting	Description
------------	-------------

Index	Shows the index of the event.
--------------	-------------------------------

Bootup Number	Shows the total number of times the device has been powered on. The number increases by 1 every time the device is powered on.
----------------------	--

Severity	Shows the severity categorization of the event.
-----------------	---

Timestamp	Shows the time of the event, including the date, time, and UTC time zone adjustment.
------------------	--

Uptime	Shows the uptime of the device after it is powered on.
---------------	--

Message	Shows additional information about the event, based on the type of event. The username of the account will also be recorded for the following events: Login Success , Login Fail , User Logout .
----------------	---

Event Logs - Oversize Action

Menu Path: Diagnostics > Event Logs and Notifications > Event Logs - Oversize Action

This page lets you configure the system's oversize action when the event log reaches its maximum number of entries.

Oversize Action

The screenshot shows the 'Event Logs' configuration page with the 'Oversize Action' tab selected. The 'Oversize Action' dropdown is set to 'Overwrite the oldest event log'. The 'Capacity Warning' dropdown is set to 'Disabled'. The 'Warning Threshold' is set to '80' with a range of '50 - 100 %'. An 'APPLY' button is visible at the bottom of the configuration area.

UI Setting	Description	Valid Range	Default Value
Oversize Action	Select the action to take when the event log reaches its maximum number of entries. <ul style="list-style-type: none">• Overwrite the oldest event log: New events will overwrite the oldest events.• Stop recording event log: No new events will be recorded. This will also disable port monitoring.	Overwrite the oldest event log / Stop recording event log	Overwrite the oldest event log
Capacity Warning	Enable or disable capacity warnings.	Enabled / Disabled	Disabled
Warning Threshold	Set the warning threshold as a percentage. When Capacity Warning is enabled, a warning event log will be triggered when the event log reaches this threshold.	50% to 100%	80%

Event Logs - Backup

Menu Path: Diagnostics > Event Logs and Notifications > Event Logs - Backup

This page lets you back up the event logs through various methods.

Event Logs - Backup Settings - Local

If **Method** is set to **Local**, these settings will appear. Click **BACK UP** to save the event logs to your local computer.

Method *
Local

BACK UP

UI Setting	Description	Valid Range	Default Value
Method	Select a method for backing up event logs.	Local / TFTP / SFTP / USB	Local

Event Logs - Backup Settings - TFTP

If **Method** is set to **TFTP**, these settings will appear. Click **BACK UP** to save the event log to the specified TFTP server.

Method *
TFTP

Server IP Address * File Name *

BACK UP

UI Setting	Description	Valid Range	Default Value
Method	Select a method for backing up event logs.	Local / TFTP / SFTP / USB	Local
Server IP Address	Specify the IP address of the TFTP server to upload the event logs to.	Valid IP address	N/A
File Name	Specify a file name to use for the event logs file.	File name can only contain A-Z, a-z, 0-9 or the symbols -._().	N/A

Event Logs - Backup Settings - SFTP

If **Method** is set to **SFTP**, these settings will appear. Click **BACK UP** to save the event log to the specified SFTP server.

UI Setting	Description	Valid Range	Default Value
Method	Select a method for backing up event logs.	Local / TFTP / SFTP / USB	Local
Server IP Address	Specify the IP address of the SFTP server to upload the event logs to.	Valid IP address	N/A
File Name	Specify a file name to use for the event logs file.	File name can only contain A-Z, a-z, 0-9 or the symbols -._().	N/A
Account	Enter the SFTP server account name to use to connect to the SFTP server.	N/A	N/A
Password	Enter the SFTP server account password to use to connect to the SFTP server.	N/A	N/A

Event Logs - Backup Settings - USB

If **Method** is set to **USB**, these settings will appear. Click **BACK UP** to save the event log to an ABC-02 configuration tool connected to your device's USB port.

Note

To use this feature, USB Function must be enabled in System > Management Interface > Hardware Interface.

UI Setting	Description	Valid Range	Default Value
Method	Select a method for backing up event logs.	Local / TFTP / SFTP / USB	Local

Event Logs - Backup Settings - microSD

If **Method** is set to **microSD**, these settings will appear. Click **BACK UP** to save the event log to a microSD card inserted into your device's microSD slot.

Note

To use this feature, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.

UI Setting	Description	Valid Range	Default Value
Method	Select a method for backing up event logs.	Local / TFTP / SFTP / USB	Local

Auto Event Log Backup

When **Automatically Back Up** is enabled, when the event log is full, the earliest 1000 event logs will be backed up to an inserted ABC-02 configuration tool or microSD card and then deleted from the device.

Note

To use an ABC-02 configuration tool, USB Function must be enabled in System > Management Interface > Hardware Interface.

To use a microSD card, microSD Function must be enabled in System > Management Interface > Hardware Interfaces.

Note

If both an ABC-02 configuration tool and a microSD card are inserted into the device, the ABC-02 configuration tool will be used.

UI Setting	Description	Valid Range	Default Value
Automatically Back Up	Enable or disable automatic backup of your event logs.	Enabled / Disabled	Enabled

About Event Notifications

Event Notifications act like an alert system for the network. They allow you to be proactively notified when important events occur on the device or for other network devices connected to it.

Event Notifications

Menu Path: Diagnostics > Event Logs and Notifications > Event Notifications

This page lets you configure notifications for various kinds of events.

This page includes these tabs:

- System and Functions

- Port

Event Notifications - System and Functions

Menu Path: Diagnostics > Event Logs and Notifications > Event Notifications - System and Functions

This page lets you configure notification settings for various system events related to the overall functions of the device. Each event can be configured independently with different warning methods and severity classifications.

Event Notifications List

Search				
Group	Event Name	Enabled	Severity	Registered Action
General	Cold start	Enabled	Critical	Trap, Email
General	Warm start	Enabled	Notice	Trap, Email

Syslog

Syslog allows you to centralize event logs on a dedicated server. This provides a more comprehensive record of network activity compared to the limited storage on an individual device, aiding in troubleshooting and security analysis.

When an event occurs, an event notification can be sent as a syslog UDP packet to specified syslog servers. Each syslog server can be enabled individually.

Administrators can manually import self-signed certificates for syslog client services. However, they should check the root certificate and validity of the signature before importing, according to the organization's security procedures and requirements. After importing a certificate, the administrator should check if the certificate has been revoked and if so, the certificate must be replaced. When the device sends an imported certificate to the syslog server, the syslog server will attempt to verify the certificate against the approved certificate pool on the server.

Syslog

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#) > [Syslog](#)

This page lets you manage your device's Syslog.

This page includes these tabs:

- General
- Authentication

 **Note**

In order to ensure the security of your network, we recommend the following:

- The encryption algorithm of keys should be selected based on internationally recognized and proven security practices and recommendations.
- The lifetime of certificates generated for syslog client services should be short and in accordance with the organization's security procedures and requirements.
- For security reasons, it is recommended to send event logs to a centralized syslog server for continuous network event monitoring.

Syslog - General

Menu Path: [Diagnostics > Event Logs and Notifications > Syslog - General](#)

This page lets you configure the Syslog server settings.

Syslog Settings

 **Note**

If the syslog server cannot receive previous logs, it is possible that the receiving port of the syslog server is not ready. We suggest you enable the Linkup Delay function to delay the log delivery time.

About SNMP Trap/Inform

SNMP Trap allows an SNMP agent to notify the NMS of a significant event.

Your device supports two SNMP modes: **Trap** mode and **Inform** mode.

SNMP Trap/Inform allows your switch to actively send real-time notifications about critical events to network management systems. This proactive alerting can help identify and address network issues faster, improving overall network health and uptime.

SNMP Trap/Inform

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#) > [SNMP Trap/Inform](#)

This page lets you configure the SNMP Trap/Inform notification feature.

This page includes these tabs:

- General
- SNMP Trap/Inform Accounts

SNMP Trap/Inform - General

Menu Path: [Diagnostics](#) > [Event Logs and Notifications](#) > [SNMP Trap/Inform - General](#)

This page lets you configure the SNMP Trap/Inform settings of your device.

Click **APPLY** to save your changes.

SNMP Trap/Inform Recipients

MMS

A Manufacturing Message Specification (MMS) server allows Ethernet switches to be controlled, monitored, and managed via a Power SCADA system without the need for any additional network management software. MMS clients can receive data objects sent from a server, such as IEDs receiving data objects from a SCADA, or a SCADA receiving objects from a switch.

This device supports MMS protocol and can act as an MMS server.

Connecting With an MMS Server

To connect with an MMS server, the following key parameters need to be set:

1. **IP Address and Port**
 - a. **IP Address:** The network address of the MMS server.
 - b. **Port Number:** Typically, MMS communication uses **port 102**, though this can vary depending on the server configuration.
2. **Remote AP ID (Application Process Identifier)**
 - a. A unique identifier used in MMS communication to identify a specific application process on a remote device, such as an MMS server or an IED. The Remote AP ID typically includes the **AP Title** (Application Process Title) and **AE Qualifier** (Application Entity Qualifier). Together, these form the full identifier for the application process on the remote system.
3. **Local AP ID (Application Process Identifier)**

- a. A unique identifier used in MMS and OSI-based communication to identify the application process on your client device during communication.
4. **OSI Layer Parameters** Since MMS is based on the OSI model, specific OSI parameters are needed:
- a. **PSEL (Presentation Selector)**
 - b. **SSEL (Session Selector)**
 - c. **TSEL (Transport Selector)** These selectors define how data is routed at different layers of the OSI model.

Parameter	Setting recommended
Remote P Selector	No limitation
Remote S Selector	1
Remote T Selector	No limitation
Local P Selector	1
Local S Selector	1
Local T Selector	1

5. **Authentication Information Such as Certificate-based Authentication** Refer to [MMS - Security](#) for more information about security settings.

MMS

Menu Path: Industrial Application > IEC 61850 > MMS

Import Client Certificate	Import a client certificate file from your local computer	Valid client certificate file	N/A

About GOOSE Check

GOOSE Check is a proprietary Moxa feature, which detects tampering in GOOSE packets and optionally takes action on detection.

GOOSE (Generic Object Oriented Substation Event) messaging is a method for high-speed, event-driven communication between Intelligent Electronic Devices (IEDs) in a substation. These messages are used to transmit critical data like protection trips, status changes, and control commands with minimal delay.

GOOSE communication failures are traditionally difficult for engineers to troubleshoot over Ethernet.

To facilitate troubleshooting and increase security, the feature checks for two types of tampering:

- Port Tampering: GOOSE Packets with the same **GOOSE Address (DA)** (Destination Address) and **APPID**, but different source ports

- Source Address (SA) Tampering: GOOSE Packets with the same **GOOSE Address (DA)** and **APPID**, but different MAC Source Addresses (MAC SA)

Where both port and source address tampering are detected, packets are treated as port-tampered.

When **GOOSE Check** is enabled, anomalies are saved in the event log, and may trigger other user-specified actions, such as dropping packets or disabling the port that delivers the packets. Disabled ports may be reactivated manually.

GOOSE Check uses monitoring entries to validate GOOSE packets. Entries come from two sources:

- Static Entries: User-specified entries under the **Settings** tab. Static entries are visible in both the **Settings** and **Status** tabs
- Dynamically: When **GOOSE Lock** is disabled, the device automatically populates the list based on received packets. Dynamic entries are shown in the **Status** tab only. Dynamic learning considers the first set of values received for any given entry to be genuine.

Static entries still employ dynamic learning to learn **Ingress Port** and MAC Source Addresses (MAC SA). Learned **Ingress Port** entries are shown in the **Status** tab, while MAC Source Addresses (MAC SA) are not visible in the UI.

GOOSE Lock

GOOSE Lock is a feature that operates in addition to **GOOSE Check**, and uses an allowlist paradigm to create a tamper-evident digital seal. GOOSE packets not on the allow list trigger **Lock Violation: Warning** on the **Status** tab. This warning persists until the device is rebooted or the feature is reset. Specifically, the allowlist uses the following entry fields from the **Status** tab:

- **APPID**
- **GOOSE Address (DA)**

GOOSE packets not matching the above fields will trigger **Lock Violation: Warning** under the **Status** tab when **GOOSE Lock** is enabled. All elements must correspond to single entry, and cannot be mixed between entries.

Enabling **GOOSE Lock** freezes dynamic learning.

Important: Dynamic learning recommended before enabling **GOOSE Lock** to avoid excessive logging and possible interruptions.

Since **Ingress Port** can only be learned dynamically—even for Static Entries—enabling **GOOSE Lock** without prior dynamic learning will cause **GOOSE Check** to register all GOOSE packets as port-tampered. Without prior dynamic learning, choosing a GOOSE Check **Tamper Response** other **No Action** will result in blocking all GOOSE Packets and possibly disabling the ports. Choosing **No Action** will result in logging activity.

To avoid this, a period of dynamic learning should be permitted before enabling **GOOSE Lock**. During the dynamic learning period, monitor the **Status** tab carefully to ensure correct population of the monitoring table.

Configuring GOOSE Check

Verify GOOSE packets and take action on packets suspected of tampering.

Users planning to use GOOSE Lock should make sure that there are active GOOSE packets on the network to populate the monitoring table through dynamic learning. GOOSE Lock freezes dynamic learning, and enabling the feature prematurely may cause unwanted blocking behavior.

1. Sign in to the device with administrator credentials.
2. Go to **Industrial Application > IEC 61850 > GOOSE Check**, and then click **Settings**.
3. Under **GOOSE Check**, choose **Enabled** from the drop down.

GOOSE Lock and **Tamper Response** appear.

4. Configure the following options:

Option	Values
GOOSE Lock	<ul style="list-style-type: none">• Disabled: Allows continuous dynamic learning in addition to static entries.• Enabled: Freezes dynamic learning. Compares GOOSE Packets to APPID and GOOSE Address (DA) fields on the Status tab table. GOOSE packets not corresponding to a monitoring table entry will trigger Lock Violation: Warning, visible from Status.

Option	Values
Tamper Response	<ul style="list-style-type: none"> • No Action: Suspected tampering logged, no further action taken. • Drop: Drops packets suspected of tampering. • Port Disable: Disables ports transmitting packets suspected of tampering.

 **Note**

Important: Dynamic learning recommended before enabling GOOSE Lock to avoid excessive logging and possible interruptions.

Since Ingress Port can only be learned dynamically—even for Static Entries—enabling GOOSE Lock without prior dynamic learning will cause GOOSE Check to register all GOOSE packets as port-tampered. Without prior dynamic learning, choosing a GOOSE Check Tamper Response other No Action will result in blocking all GOOSE Packets and possibly disabling the ports. Choosing No Action will result in logging activity.

To avoid this, a period of dynamic learning should be permitted before enabling GOOSE Lock. During the dynamic learning period, monitor the Status tab carefully to ensure correct population of the monitoring table.

5. Before continuing, click **Apply** to save your settings.

6. To add static entries to the Monitoring table, click  **[Add]**.

The Create Static GOOSE Entry screen appears.

7. Specify an **APP ID** in hex and a **GOOSE Address (DA)**, and then click **Apply**.

GOOSE Address (DA) prefills the first four octets 01:0C:CD:01:, requiring two octets.

 **Note**

GOOSE Check detects tampering by checking entries against learned Source Port and Source Address - which manual entries cannot specify. If used in conjunction with GOOSE Lock, a period of dynamic learning should be permitted before enabling GOOSE Lock to ensure proper functionality.

GOOSE packets not matching both parameters will trigger **Tamper Response** actions.

8. **Optional:** Continue to add entries until the table matches your network requirements.

- To check the current state of GOOSE Check packets, go to **Industrial Application > IEC 61850 > GOOSE Check** and then click **Status**.

- To re-enable ports disabled by **Tamper Response Port Disable**, go to **Port > Port Interface > Port Settings**, click **[Edit]** corresponding to the disabled port, and then set **Admin** to **Enabled**. Click **Apply** to save your changes.

GOOSE Check

Menu Path: Industrial Application > IEC 61850 > GOOSE Check

<small>Hex digits only</small>	

CANCEL **APPLY**

UI Setting	Description	Valid Range	Default Value
APP ID	Specify the application identifier for the GOOSE message.	Hex values from 0000 to ffff	N/A
GOOSE Address (DA)	Specify the destination MAC address for the GOOSE message.	01-0C-CD-01-00-00 to 01-0C-CD-01-01-ff	N/A

Deleting a GOOSE Check Monitoring Entry

Menu Path: Industrial Application > IEC 61850 > GOOSE Check - Settings

You can delete an entry by using the checkboxes to select the entries you want to delete, then clicking the **Delete (🗑)** icon.

GOOSE Check - Status

Menu Path: Industrial Application > IEC 61850 > GOOSE Check - Status

This page lets you view the current GOOSE check status of the device.

Monitoring Table Status

Monitoring Table Status ↻

GOOSE Lock Status: Disabled Lock Violation Status: Normal i

UI Setting	Description
GOOSE Lock Status	Shows whether GOOSE lock is enabled.
Lock Violation Status	Shows the current GOOSE lock violation status. This status is automatically refreshed every 5 minutes. <ul style="list-style-type: none"> Normal: All detected GOOSE packets are shown in the monitoring table. Warning: Unexpected GOOSE packets were detected that are not be shown in the monitoring table.

GOOSE Message List

↻
🔍 Search

<input type="checkbox"/>	Type	APP ID	GOOSE Address (DA)	GoCB Name	VLAN ID	Ingress Port	Rx Counter	Status
Items per page: 50 0 of 0 < < > >								

UI Setting	Description
Type	Shows the type of the ingress GOOSE message. <ul style="list-style-type: none"> Static: The GOOSE message is defined on this device. Dynamic: The GOOSE message is learned from GOOSE packets.
APP ID	Shows the application identifier of the ingress GOOSE message.
GOOSE Address (DA)	Shows the destination MAC address of the ingress GOOSE message.
GoCB Name	Shows the IED name and GOOSE control block name of ingress GOOSE packets.

UI Setting	Description
VLAN ID	Shows the VLAN ID of the ingress GOOSE message.
Ingress Port	Shows the ingress port of the GOOSE message.
Rx Counter	Shows the packet counter of the ingress GOOSE message.
Status	Shows the communication status of the GOOSE message. <ul style="list-style-type: none"> • Healthy: The communication status is normal. • Timeout: The communication status is abnormal. This GOOSE message did not pass through the device at the correct time. • Tampered: There has been possible packet tampering, because there were GOOSE packets with the same DA and APP ID that came from different source ports, or there were GOOSE packets with the same destination address (DA) and APP ID but different source addresses (SA) that came from different source ports.

About Modbus TCP

Modbus is a vendor neutral and commonly used communication protocol to monitor and control industrial automation equipment such as PLCs, sensors, and meters. It is a messaging structure used to establish multiple client-server applications to monitor or program devices.

In order to be fully integrated into industrial systems, Moxa's switches support the Modbus TCP/IP protocol for real-time monitoring in a SCADA system.

Modbus In Depth

Modbus uses a client/server communication structure that is based on transactions built between client and server. The client requests to read or write server data and the server replies with a message to confirm after completing the instruction.

The message format between client/server at a minimum must include a Protocol Data Unit (PDU) and may also include an Application Data Unit (ADU). The PDU includes function code and data. The function code is the instruction code to read or write server data, and the data includes related parameters for the instruction, such as reading the data in certain addresses.

Moxa switches can act as a Modbus server to reply to Modbus clients like a SCADA.

- Supports up to 5 simultaneous connections from clients
- Closes a connection when there are no Modbus TCP requests received through the connection for 60 seconds
- Closes all Modbus TCP connections within 5 seconds when all switch ports are link down
- Supports Function Code 4 with 16-bit (2-word) data access for read-only information

Data Access Type		Function Code	Function Name
Word access (16-bit access)	Physical input registers	4	Read input registers

Information that clients can request:

- System information
- Port information
- Packet information
- Redundancy information

Refer to [Modbus Data Map and Information](#) for detailed data maps and more information.

About EtherNet/IP

EtherNet/IP is a commercial-off-the-shelf industrial protocol based on IEEE 802.3 combined with the TCP/IP Suite managed by the ODVA association.

EtherNet/IP follows the OSI model and implements Common Industrial Protocol (CIP). CIP is an object-oriented protocol and ODVA defining several communication objects in CIP. Moxa switches support a subset of these objects as a device role in EtherNet/IP ecosystem.

EtherNet/IP is widely adopted as a standard communication protocol among devices in industrial ecosystems. For example, Rockwell Automation uses EtherNet/IP as the standard protocol for their Logix controllers over Ethernet networks. Moxa switches also provide EtherNet/IP features to integrate with the Rockwell system and monitor the status of switches and PLCs, making switches a part of the Rockwell system.

About PROFINET

PROFINET is an open industrial Ethernet communication protocol proposed by PROFIBUS & PROFINET International (PI), an organization dedicated to industrial communication standards. It is fully compatible with Ethernet as defined in the IEEE standard and has

been included in the IEC 61158 and IEC 61784 standards since 2003. PROFINET enables the implementation of applications for production and process automation, safety applications, and a wide range of drive technology.

Node Roles

PROFINET includes three node roles:

- **IO-Controllers:** IO-Controllers control the automated tasks of IO-Devices and collect relevant information for users.
- **IO-Supervisors:** IP-supervisors are usually PC-based software and allow users to configure parameters and diagnose the status of individual modules. IO-Supervisors do not participate directly in routine operations.
- **IO-Devices:** IO-Devices are controlled and monitored by IO-Controllers, and may include several modules or submodules. A device model describes all field devices in terms of their possible technical and functional features. A device model is specified by the DAP (Device Access Point) and the defined modules for a particular device family. A DAP is the access point for communication with the Ethernet interface and the processing program.
 - This Moxa device is a PROFINET I/O device.

GSD Files

General Station Description (GSD) files for the field devices to be configured are required for system engineering. A GSD is an XML-based file that describes the properties and functions of the PROFINET I/O field devices. It contains data relevant for engineering as well as for data exchange with the device.

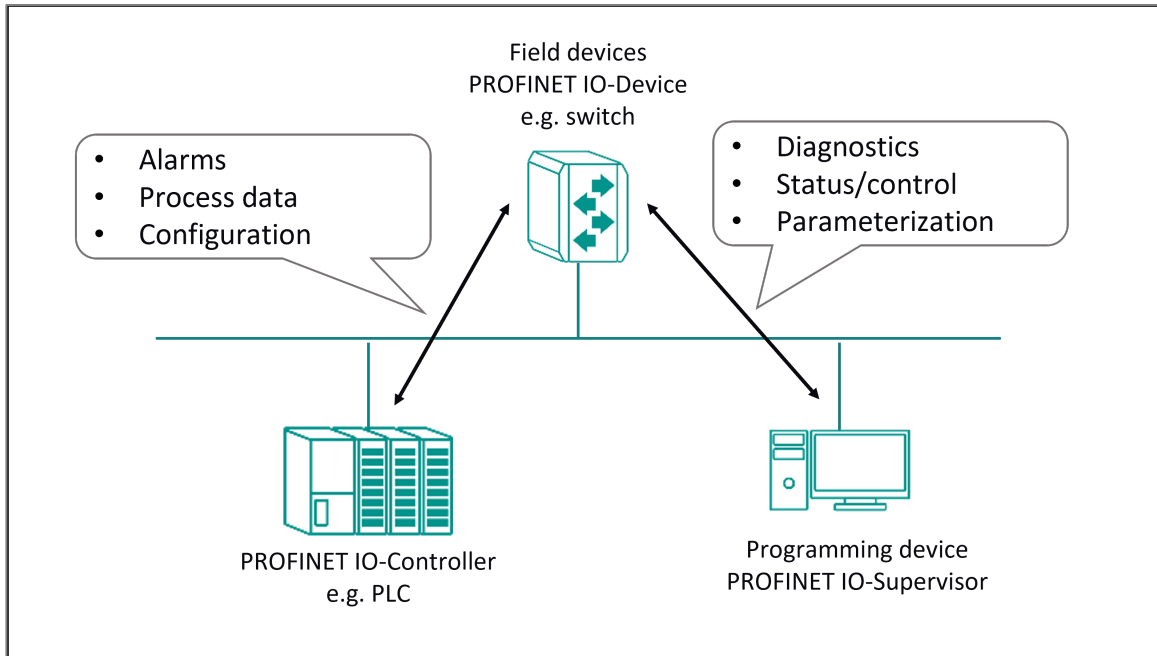

You can download the field device GSD file for this device from the Moxa website.

PROFINET In Depth

PROFINET IO operates through IO-Supervisors, IO-Controllers, and IO-Devices, and can fulfill various levels of requirements through periodic and aperiodic data transmission.

IO-Devices are standalone units designed to transmit real-time (RT) information to IO-Controllers (PLCs). They do not attempt to communicate directly with other devices.

Instead, they directly provide their real-time (cyclic) data to an IO-Controller and may send some alarm or diagnostic (acyclic) data to an IO-Supervisor.

PROFINET Attributes and TIA Portal Integration

Addressing of I/O Data in PROFINET I/O Based on Slot and Sub-Slots

The concept of the Moxa PROFINET switch is shown in the table below. In this structure, each switch port represents one sub-slot.

Slot 0					
Sub Slot 0	Sub Slot 0X8000	Sub Slot 0X8001	Sub Slot 0X8002	Sub Slot 0X8003	...
DAP	IO Data	Port 1	Port 2	Port 3	...

Manufacturer Information

Each PROFINET device is addressed based on a MAC address. This address is unique worldwide. The company code (bits 47 to 24) can be obtained from the IEEE Standards Department free of charge. This part is called the OUI (organizationally unique identifier).

MOXA OUI Table:

Bit Value 47..24						Bit Value 23..0					
0	0	0	2	2	9	x	x	x	x	x	x
Company Code (OUI)						Consecutive Number					

PROFINET Attributes

Combined with the General Station Description (GSD) file, an IO-Controller can quickly configure settings for different devices and seamlessly replace devices. A PROFINET IO General Station Description (GSD) file is a description of an IO-Device provided by the device manufacturer. The contents of the GSD file contain configuration information, parameters, modules, diagnostics and alarms, and vendor and device identification.

PROFINET Cyclic I/O Data Table

- **Device Status**

Category	Direction	Byte	Bit	Name	Description
Device	Input	0	0	Device status	0 is failed status, 1 is OK.
			1	Power 1	0 is unavailable, 1 is OK
			2	Power 2	0 is unavailable, 1 is OK
Device	Input	1	Reserved for redundancy protocol		

- **Port Status**

Category	Direction	Byte	Bit	Name	Description
Port	Input	0	0	Port 1 Connection	0 is not connected, 1 is connected

Category	Direction	Byte	Bit	Name	Description
			1	Port 2 Connection	0 is not connected, 1 is connected
			2	Port 3 Connection	0 is not connected, 1 is connected
			{ ... }	{ ... }	{ ... }
			7	Port 8 Connection	0 is not connected, 1 is connected

"Cyclic Data - Port 12"	%I3.3	Bool	FALSE			
"Cyclic Data - Port 13"	%I3.4	Bool	TRUE			
"Cyclic Data - Port 14"	%I3.5	Bool	TRUE			

PROFINET I/O Parameters

Moxa defines comprehensive PROFINET I/O parameters for more flexible settings and monitoring. The attributes are readable or writable. PROFINET I/O parameters use PROFINET acyclic data to achieve communication in the network. You can use the TIA Portal tool or engineering deployment software to edit it.

There are 2 categories of parameters, including Device Status and Device Alarms.

The following tables provide parameter information:

- r/w: Read and Write
- ro: Read Only

Device Status

Byte	Name	Access	Value	Description
0	PLC Connection Status	ro	0	Unavailable
			1	Connection failure
			2	OK
1	PLC Connection Status	ro	0	Unavailable
			1	Device detect fault
			2	OK
2	Power 1 Status	ro	0	Unavailable

Byte	Name	Access	Value	Description
			1	Power 1 fails
			2	OK
3	Power 2 Status	ro	0	Unavailable
			1	Power 2 fails
			2	OK
4	DI 1 Status	ro	0	Unavailable
			1	Closed
			2	Open
5	DI 2 Status	ro	0	Unavailable
			1	Closed
			2	Open
6	Spanning Tree Config	ro	0	Unavailable
			1	Disable
			2	RSTP
			3	MSTP
7	Turbo Ring v2 Config	ro	0	Unavailable
			1	Disable
			2	Enable
8	Turbo Ring v2 Ring 1 Config	ro	0	Unavailable
			1	Disable
			2	Enable

			4	Primary path sensing recovery
14	Media Redundancy Protocol Config	ro	0	Unavailable
			1	Disable
			2	Enable
15	Media Redundancy Protocol Manager Status	ro	0	Unavailable
			1	Disable

Byte	Name	Access	Value	Description
			2	Initiation
			3	Awaiting Connection
			4	Primary Ring Port Link Up
			5	Ring Open
			6	Ring Closed
16	Media Redundancy Protocol Client Status	ro	0	Unavailable
			1	Connection failure
			2	OK
			3	Awaiting Connection
			4	Data Exchange Idle
			5	Pass Through
			6	Data Exchange
			7	Pass Through Idle

Device Alarms

These parameters control PROFINET Alarm functions. A PROFINET alarm is a message which is sent from the switch to a PLC immediately once the event is triggered.

Byte	Name	Access	Value	Description	Default Value
0	Status Alarm	rw	0	Do not send any alarms	0: No alarms
			1	Send alarm if any status change	
1	Power Alarm 1	rw	0	Do not send power failed alarm	0: No alarms
			1	Send alarm if power supply 1 fails	
2	Power Alarm 2	rw	0	Do not send power failed alarm	0: No alarms

Byte	Name	Access	Value	Description	Default Value
			1	Send alarm if power supply 2 fails	
3	RSTP Topology Changed Alarm	rw	0	Do not send RSTP topology changed alarm	0: No alarms
			1	Send alarm if RSTP topology changed	
4	MSTP Topology Changed Alarm	rw	0	Do not send MSTP topology changed alarm	0: No alarms
			1	Send alarm if MSTP topology changed	
5	Turbo Ring V2 Ring Broken	rw	0	Do not send TR2 broken alarm	0: No alarms
			1	Send alarm if TR2 is broken	
6	MRP Ring Broken	rw	0	Do not send MRP broken alarm	0: No alarms
			1	Send alarm if MRP is broken	

Reset to Factory Mode

The following table is the list of Reset to Factory Modes supported by MOXA:

Reset to Factory Modes	Mode Description	Action taken
Mode 0 - Factory Default Mode	Original Factory Reset	Cleans all configured settings including PROFINET
Mode 1	Reset Application data	Resets I&M data and the alarm configuration of devices and ports
Mode 2	Reset Communication parameter	Resets Device Name to " " and IP to 0.0.0.0
Mode 3	Reset Engineering parameter	Performs Mode 1, 2, and clears all configured settings

CIP EtherNet/IP Objects

Several communication objects are defined in CIP (Common Industrial Protocol).

Moxa switches support the following objects for PLCs and SCADA systems to monitor:

Definition	CIP Object Name	Class ID
ODVA	Identity Object	0x01
	Message Router	0x02
	Assembly	0x04
	Connection Manager Object	0x06
	Base Switch Object	0x51
	Port Object	0xF4
	TCP/IP Interface Object	0xF5
	Ethernet Link Object	0xF6
	LLDP Management Object	0x109
	LLDP Data Table Object	0x10A
MOXA	Moxa Networking Object (Vendor Specific)	0x404

The supported attributes and services of the above objects are introduced in the table below, including Each object should consist of Class ID, Instance ID, Attribute ID, and Service Code. The supported attributes and services of the above objects are introduced in the following chapters, including the access rules, data type, and description for each attribute.

Identity Object

The Class code of Identity object is **0x01**.

There is **one** instance of this object in our product. It stores the information of the production and the device. The following tables summarize the class attribute, instance attributes, and service code.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object
2	Get	Max Instance	UINT (16)	Maximum instance number of an object currently created in this class level of the device
3	Get	Number of Instances	UINT (16)	Number of object instances currently created in this class level of the device.
6	Get	Maximum ID Number Class Attributes	UINT (16)	Maximum class attribute ID number implemented in the device
7	Get	Maximum ID Number Instance Attributes	UINT (16)	Maximum instance attribute ID number implemented in the device

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Vendor ID		UINT (16)	0x3DF , the vendor ID of Moxa is 991.
2	Get	Device Type		UINT (16)	0x2C , "Managed Ethernet Switch".
3	Get	Product Code		UINT (16)	Please refer to Product Code Table.
4	Get	Revision		(Struct.)	Revision of the item the Identity Object represents.
			Major	USINT (8)	The structure member, major. The value zero is not valid. If product version is 0, using 1-base.
			Minor	USINT (8)	The structure member, minor. The value zero is not valid. If product version is 0, using 1-base.
5	Get	Status		WORD (16)	Summary status of the device.
6	Get	Serial Number		UDINT (32)	The serial number of each device.
7	Get	Product Name		SHORT_STRING	The product model of the Moxa switch. Maximum length is 32 characters.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
15	Get/Set	Assigned Name		STRINGI	Switch device's host name.
17	Get/Set	Geographic Location		STRINGI	The assigned switch location.

The Identity Object Instance supports the following CIP Common services:

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
				0x01 ✓ ✓ Get_Attributes_All Returns the contents of all attributes of the class.
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x10		✓	Get_Attribute_Single	Used to write an object instance attribute.
0x05		✓	Reset	Invokes the reset service for the device.
0x18		✓	Get_Member	Returns the content of a selected member of an attribute.

Message Router Object

The Class code of Message Router Object is **0x02**. The object within a node that distributes messaging requests to the appropriate application objects.

The supported messaging connections are as the following:

- Explicit Messaging
- Unconnected Messaging
- Implicit messaging

When using the UCMM to establish an explicit messaging connection, the target application object is the Message Router object.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (2)	Revision of this object

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Object_list		(Struct.)	A list of supported objects
			Number	UINT (16)	Number of supported classes in the classes array
			Classes	Array of UINT (16)	List of supported class codes
2	Get	Number Available		UINT (16)	Maximum number of connections supported
3	Get	Number Active		UINT (16)	Number of connections currently used by system components
4	Get	Active Connections		Array of UINT (16)	A list of the connection IDs of the currently active connections

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E		✓	Get_Attribute_Single	Used to read an object instance attribute.

Assembly Object

The Moxa switch support **static** assembly object for CIP I/O messaging.

The Class code is **0x04**.

There are three instances of this object as the following.

	Instance Number	Size (32 bit)
Output	1	18
Input	50	16
Configuration	100	10

The **Input** means the data is produced by switch which includes the information and status report to the originator for monitoring. The **Output** means the data is generated by the originator (remote host) and is consumed by switch.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object

Instance Attribute List

Attr ID	Access Rule	Name	Data Type	Description
3	Get/Set	Data	Array of BYTE	The implicit messaging content
4	Get	Size	UINT (16)	Number of bytes in Attr. 3

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute

For the definition of the I/O messaging, see the following table for details.

I/O Assembly Data Attribute Formats

Direction	Instance	Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Input	1	0	Power Source Status (Least Significant Byte)							
		1	Power Source Status (Most Significant Byte)							
		2-5	Global Link Status DWORD 0							
		6-9	Global Link Status DWORD 1							
		10-13	Global Link Status DWORD 2							
Output	50	0-3	Global Admin State DWORD 0							
		4-7	Global Admin State DWORD 1							
		8-11	Global Admin State DWORD 2							
		12-15	Global Admin State DWORD 3							

Mapping I/O Assembly Data Attribute Components

The following table indicates the I/O assembly Data attribute mapping for the Managed Ethernet Switch device.

Service Code	Class	Instance	Attribute Name	Attribute Number
Power Source Status	Base Switch Object	1	Power Source	4
Global Admin State			Global Port Admin State	7
Global Link Status			Global Port Link Status	8

Connection Manager Object

The class code of Connection Manager Object is **0x06**. The Connection Manager Object allocates and manages the internal resources associated with both I/O and Explicit Messaging connections. There is one instance of this object. The supported connection trigger type is cyclic and change of state (COS).

The instance attribute list is introduced as the following.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object.

Instance Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get/Set	Open Requests	UINT(16)	<p>Number of Forward_Open service requests received.</p> <p>A device may reject a set request to this attribute, using General Status Code 0x09 (Invalid Attribute Value), if the attribute value sent is not zero.</p> <p>(Vol1_3.33 3-5.2 Instance Attributes)</p>

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0e	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute.
0x4E		✓	Forward_Close	Closes a connection.
0x54		✓	Forward_Open	Opens a connection. Maximum data size is 511 bytes.

QoS Object

The QoS Object provides a means to configure certain QoS-related behaviors in EtherNet/IP devices. The class code of QoS Object is 0x48. The following table defines the default DSCP mappings for EtherNet/IP.

Traffic Type	CIP Priority	DSCP	CIP Traffic Usage (Recommended)
CIP class 0/1 • CIP UCMM • CIP class 2/3 • All other EtherNet/IP Encapsulation messages	Urgent (3)	55	CIP Motion
	Scheduled (2)	47	Safety I/O I/O
	High (1)	43	I/O
	Low (0)	31	No recommendation at present
	All	27	CIP messaging

Class Attribute

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object.

Instance Attribute

Attr ID	Access Rule	Name	Data Type	Description
4	Get/Set	DSCP Urgent	USINT (8)	CIP transport class 0/1 messages with Urgent priority
5	Get/Set	DSCP Scheduled	USINT (8)	CIP transport class 0/1 messages with Scheduled priority
6	Get/Set	DSCP High	USINT (8)	CIP transport class 0/1 messages with High priority
7	Get/Set	DSCP Low	USINT (8)	CIP transport class 0/1 messages with Low priority
8	Get/Set	DSCP Explicit	USINT (8)	CIP UCMM CIP transport class 2/3 All other EtherNet/IP encapsulation messages

Any change to the value of the above attributes will only take effect after the device is restarted.

Common Service

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute.

Base Switch Object

The class code of Base Switch Object is 0x51. The Base Switch Object provides the CIP application-level interface and basic status information for a Managed Ethernet switch device.

Devices shall implement no more than one instance of the Base Switch Object.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object. The current value assigned to this is 1.

Instance Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Device Up Time	UDINT (32)	Time since device was powered up.
2	Get	Total Port Count	UDINT (32)	Number of physical available ports.
3	Get	System Firmware Version	SHORT_STRING	Human readable representation of System Firmware Version. Maximum length is 32 characters.

Attr ID	Access Rule	Name	Data Type	Description
4	Get	Power Source	WORD (16)	<p>Status of switch power source.</p> <p>Bits 0-1: State of the Power Source 1.</p> <p>00 = Not Present (Power source not present in switch)</p> <p>01 = Not Powered (Power source present but not powered)</p> <p>10 = Faulted(internal) (Power source present but faulted)</p> <p>11 = Powered and ok (Power source present, powered, and OK)</p> <p>Bits 2-3: State of the Power Source 2. The values are same as bits 0-1.</p> <p>Bits 4-5: State of the Power Source 3. The values are same as bits 0-1.</p> <p>Bits 6-7: State of the Power Source 4. The values are same as bits 0-1.</p> <p>Bits 8-9: State of the Power Source 5. The values are same as bits 0-1.</p> <p>Bits 10-11: State of the Power Source 6. The values are same as bits 0-1.</p> <p>Bits 12-13: State of the Power Source 7. The values are same as bits 0-1.</p> <p>Bits 14-15: State of the Power Source 8. The values are same as bits 0-1.</p>
5	Get	Port Mask Size	UINT (16)	Number of DWORDs in port array attributes. Minimum = 4, supporting 128 ports.
6	Get	Existing Port	ARRAY OF DWORD (32)	<p>Switch existing port.</p> <p>0 = Port Absent</p> <p>1 = Port Present</p>
7	Get	Global Port Admin State	ARRAY OF DWORD (32)	<p>Port Admin State.</p> <p>0 = Port Disabled</p> <p>1 = Port Enabled</p>
8	Get	Global Port Link Status	ARRAY OF DWORD (32)	<p>Ports Link Status.</p> <p>0 = Link Inactive (Down)</p> <p>1 = Link Active (Up)</p> <p>Bit 0-31: Port 0-31 Link status.</p>

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.

Port Object

The port object represents the underlying interface of CIP which is EtherNet/IP.

The class code is **0xf4**. There is one instance of this object.

The instance attribute "**Port Type**" identifies the CIP adaptation.

Class Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Revision		UINT (16)	Revision of this object
2	Get	Max Instance		UINT (16)	Maximum instance number of an object currently created in this class level of the device
3	Get	Number of Instances		UINT (16)	Number of object instances currently created at this class level of the device.
8	Get	Entry Port		UINT (16)	Returns the instance of the Port Object that describes the port through which this request entered the device.
9	Get	Port Instance Info	Port Type	UINT (16)	Enumerates the type of port.
			Port Number	UINT (16)	CIP port number associated with this port

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Port Type		UINT (16)	Enumerates the type of port. 4 = EtherNet/IP.
2	Get	Port Number		UINT (16)	CIP port number associated with this port. (Values 0-1 are reserved and cannot be used)
3	Get	Link Object	Path Length	UINT (16)	Number of 16 bit words in the following path.
			Link Path	Padded EPATH	Logical path segments that identify the object for this port.
4	Get	Port Name		SHORT_STRING	Vendor assigned name of the communications interface. The value is always "EIP Port".
5	Get	Port Type Name		SHORT_STRING	String which names the port type. If Port Type value is 4 (EtherNet/IP), its associated Port Type Name is "EtherNet/IP". The value is always "EtherNet/IP".
7	Get	Node Address		Padded EPATH	This is a single Port Segment containing the Port Number of this port and the Link Address of this device on this port.
9	Get	Port Key		Packed EPATH	The electronic key of the chassis this port is attached to. This attribute shall be limited to format 4 of the Logical Electronic Key segment. The Vendor ID, Device Type, Product Code, Major Revision and Minor Revision fields shall not be 0. The Compatibility field shall be 0 (indicating match).
10	Get	Port Routing Capabilities		DWORD (32)	Bit string that defines the routing capabilities of this port.

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.

TCP/IP Interface Object

The Class code of TCP/IP Interface object is **0xf5**. The TCP/IP Interface Object provides the mechanism to configure a device's TCP/IP network interface. Examples of configurable items include the device's IP Address, Network Mask, and Gateway Address. There is **one** instance of this object.

The following tables summarize the attributes of this object.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object.
2	Get	Max Instance	UINT (16)	Maximum instance number of an object currently created in this class level of the device
3	Get	Number of Instances	UINT (16)	Number of object instances currently created at this class level of the device
6	Get	Maximum ID Number Class Attributes	UINT (16)	Maximum class attribute ID number implemented in the device.
7	Get	Maximum ID Number Instance Attributes	UINT (16)	Maximum instance attribute ID number implemented in the device.

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Status		DWORD (32)	Interface status 0 = The Interface Configuration attribute has not been configured. 1 = The Interface Configuration attribute contains valid configurations obtained from BOOTP, DHCP or non-volatile storage.
2	Get	Configuration Capability		DWORD (32)	Indicates the device's support for optional network configuration capability. 0 = Device is not capable. 1 = Device is capable. Bit map of capability flags: Bit 0: BOOTP Client Bit 1: DNS Client Bit 2: DHCP Client Bit 3: DHCP-DNS Update Bit 4: Configuration Settable
3	Get/Set	Configuration Control		DWORD (32)	Interface control flags Bit map of control flags: Bit 0 to 3: Startup Configuration 0 = The device shall use the interface configuration values previously stored (for example, in non-volatile memory or via hardware switches). 1 = The device shall obtain its interface configuration values via BOOTP. 2 = The device shall obtain its interface configuration values via DHCP upon start-up. 3 to15 = Reserved.
4	Get	Physical Link Object	Path Size	UINT (16)	Size of Path
			Path	Padded EPATH	Logical segments identifying the physical link object
5	Get/Set	Interface	IP Address	UDINT (32)	The device's IP address

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
		Configuration	Network Mask	UDINT (32)	The device's network mask
			Gateway Address	UDINT (32)	Default gateway address
			Name Server	UDINT (32)	Primary name server
			Name Server2	UDINT (32)	Secondary name server
			Domain Name	STRING	Default domain name. Maximum length is 48 characters. A length of 0 shall indicate no Domain Name is configured. Set Domain Name is not supported in Moxa switch.
6	Get/Set	Host Name		STRING	Host name. ASCII characters. Maximum length is 64 characters.
13	Get/Set	Encapsulation Inactivity Timeout		UNIT (16)	Number of seconds of inactivity before TCP connection is closed. Default = 120 0 = Disable timeout 1-3600 = timeout in seconds

The TCP/IP Object Instance supports the following CIP Common services:

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x01	✓	✓	Get_Attributes_All	Returns the contents of all attributes of the class
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute

Ethernet Link Object

The Class code of Ethernet Link object is **0xf6** (Defined in CIP Vol2, 5-4). For each switch port, there is an instance of this class. The following table shows the mapping of instance number and the switch port number.

Instance Number	Mapping to
0	Ethernet Link class
1	1st switch port
2	2nd switch port
3	3rd switch port
...	...

The following tables summarize the attributes of the Ethernet Link object.

There are some vendor specific attributes in the table (Starting from attribute Id 100).

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object
2	Get	Max Instance	UINT (16)	Maximum instance number of an object currently created in this class level of the device
3	Get	Number of Instances	UINT (16)	Number of object instances currently created in this class level of the device
6	Get	Maximum ID Number Class Attributes	UINT (16)	Maximum class attribute ID number implemented in the device.
7	Get	Maximum ID Number Instance Attributes	UINT (16)	Maximum instance attribute ID number implemented in the device.
100	Get	Moxa-specific Revision	UINT (16)	Revision of Moxa specific attributes and services for Linux platform switch. The current value assigned is 1.

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Interface Speed		UDINT (32)	Interface speed currently in use. The scale of the attribute is in Mbps. (Speed in Mbps, e.g., 0, 10, 100, 1000, etc.)
2	Get	Interface Flags		DWORD (32)	Refer to the Interface Flags table.
3	Get	Physical Address		ARRAY of 6 USINT (8)	Interface's MAC layer address.
4	Get	Interface Counters	In Octets	UDINT (32)	Octets received on the interface.
			In Ucast Packets	UDINT (32)	Unicast packets received on the interface.
			In NUcast Packet	UDINT (32)	Non-unicast packets received on the interface.
			In Discards	UDINT (32)	Inbound packets received on the interface but are discarded.
			In Errors	UDINT (32)	Inbound packets that contain Errors (does not include In Discards).
			In Unknown Protos	UDINT (32)	Inbound packets with unknown protocol.
			Out Octets	UDINT (32)	Octets sent on the interface.
			Out Ucast Packets	UDINT (32)	Unicast packets sent on the interface.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
			Out NUcast Packets	UDINT (32)	Non-unicast packets sent on the interface.
			Out Discards	UDINT (32)	Discarded outbound packets.
			Out Errors	UDINT (32)	Outbound packets that contain errors.
5	Get	Media Counters	Alignment Errors	UDINT (32)	Received frames that are not an integral number of octets in length.
			FCS Errors	UDINT (32)	Received frames that do not pass the FCS check.
			Single Collisions	UDINT (32)	Successfully transmitted frames which experienced exactly one collision.
			Multiple Collisions	UDINT (32)	Successfully transmitted frames which experienced more than one collision.
			SQE Test Errors	UDINT (32)	Number of times the SQE test error message is generated.
			Deferred Transmissions	UDINT (32)	Frames for which the first transmission attempt is delayed because the medium is busy.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
			Late Collisions	UDINT (32)	Number of times a collision is detected later than 512 bit times into the transmission of a packet.
			Excessive Collisions	UDINT (32)	Frames for which transmission fails due to excessive collisions.
			MAC Transmit Errors	UDINT (32)	Frames for which transmission fails due to an internal MAC sublayer transmit error.
			Carrier Sense Errors	UDINT (32)	Times that the carrier sense condition was lost or never asserted when attempting to transmit a frame.
			Frame Too Long	UDINT (32)	Received frames that exceed the maximum permitted frame size.
			MAC Receive Errors	UDINT (32)	Frames for which reception on an interface fails due to an internal MAC sublayer receive error.
6	Get/Set	Interface Control		(Struct.)	Configuration for physical Interface.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
			Control Bits	WORD (16)	Bit 0: Auto-Negotiate Value 0: Force Value 1: Auto-Nego Bit 1: Forced Duplex Mode Value 0: half duplex Value 1: full duplex Bit 2 to 15: Reserved, all zero
			Forced Interface Speed	UINT (16)	Speed at which the interface shall be forced to operate. Speed in Mbps (10, 100, 1000, etc.)
10	Get	Interface Label		SHORT_STRING	Port description. Maximum length is 64 characters.
11	Get	Interface Capability		(Struct.)	Indication of capabilities of the interface

Capability Bits	DWORD (32)	<p>Interface capabilities, other than speed/duplex.</p> <p>Bit 0: Manual Setting Requires Reset</p> <p>Value 0: The device automatically applies changes made to the Interface Control attribute (#6). Doesn't require a reset in order for changes to take effect.</p> <p>Value 1: The device doesn't automatically apply changes made to the Interface Control attribute (#6). Require a reset in order for changes to take effect.</p> <p>Bit 1: Auto-Negotiate</p> <p>Value 0: Not support AN</p> <p>Value 1: Support AN</p> <p>Bit 2: Auto-MDIX</p> <p>Value 0: Not support auto MDIX</p> <p>Value 1: Support auto MDIX</p> <p>Bit 3: Manual Speed/Duplex</p> <p>Value 0: Not support manual setting of speed/duplex.</p> <p>Value 1: Supports manual setting of speed/duplex via the Interface Control attribute (#6)</p> <p>Bit 4 to 31: Reserved, all zero</p>
-----------------	------------	--

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
		Speed/Duplex Options		(Struct.)	Indicates speed/duplex pairs supported in the Interface Control attribute.
12	Get	HC Interface Counters	HCInOctets	ULINT (64)	The total number of octets received on the interface. This counter is a 64-bit version of In Octets.
			HCInUcastPkts	ULINT (64)	Unicast packets received on the interface. This counter is a 64-bit version of In Ucast Packets.
			HCInMulticastPkts	ULINT (64)	Multicast packets received on the interface.
			HCInBroadcastPkts	ULINT (64)	Broadcast packets received on the interface.
			HCOctets	ULINT (64)	Octets sent on the interface. This counter is a 64-bit version of Out Octets.
			HCOUcastPkts	ULINT (64)	Unicast packets sent on the interface. This counter is a 64-bit version of Out Ucast Packets.
			HCOMulticastPkts	ULINT (64)	Multicast packets sent on the interface.
			HCOBroadcastPkts	ULINT (64)	Broadcast packets sent on the interface.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
13	Get	HC Media Counters	HCStatsAlignmentErrors	ULINT (64)	<p>Frames received that are not an integral number of octets in length and do not pass the FCS check.</p> <p>This counter is a 64-bit version of Alignment Errors.</p>
			HCStatsFCSErrors	ULINT (64)	<p>Frames received that are an integral number of octets in length but do not pass the FCS check. This counter is a 64-bit version of FCS Errors.</p>
			HCStatsInternalMacTransmitErrors	ULINT (64)	<p>Frames for which transmission fails due to an internal MAC sublayer transmit error.</p> <p>This counter is a 64-bit version of MAC Transmit Errors.</p>
			HCStatsFrameTooLongs	ULINT (64)	<p>Frames received that exceed the maximum permitted frame size.</p> <p>This counter is a 64-bit version of Frame Too Long Errors.</p>
			HCStatsInternalMacReceiveErrors	ULINT (64)	<p>Frames for which reception on an interface fails due to an internal MAC sublayer receive error.</p> <p>This counter is a 64-bit version of MAC Receive Errors.</p>

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
			HCStatsSymbolErrors	ULINT (64)	Number of times there was an invalid data symbol on the media when a valid carrier was present.
100	Get	Port State		USINT (8)	Switch port state. Value 1 = Disable Value 2 = Blocking Value 3 = Listening Value 4 = Learning Value 5 = Forwarding Value 6 = Broken
101	Get	Media Type		STRING	Port media type.
102	Get/Set	Traffic Storm Control		USINT (8)	Traffic storm control enable. 0 = Disabled 1 = Enabled Bit 0: Broadcast storm control Bit 1: Multicast storm control Bit 2: DLF storm control
103	Get/Set	Port On event		USINT (8)	Registered port for port on event notification. 0 = Unregistered. 1 = Registered.
104	Get/Set	Port Off event		USINT (8)	Registered port for port off event notification. 0 = Unregistered. 1 = Registered.

Attr ID	Access Rule	Name (Struct.)	Data Type	Description
105	Get/Set	Port shut down by Port Security event	USINT (8)	Registered port for port shut down by Port Security event notification. 0 = Unregistered. 1 = Registered.
106	Get/Set	Port shut down by Rate Limit event	USINT (8)	Registered port for port shut down by Rate Limit event notification. 0 = Unregistered. 1 = Registered.
107	Get/Set	Port recovered by Rate Limit event	USINT (8)	Registered port for port recovered by Rate Limit event notification. 0 = Unregistered. 1 = Registered.
108	Get/Set	Fiber Check Warning	USINT (8)	Registered port for fiber check warning event notification. 0 = Unregistered. 1 = Registered.

Interface Flags

Bit(s)	Called	Definition
0	Link Status	0 indicates an inactive link; 1 indicates an active link.
1	Half/Full Duplex	0 indicates half duplex; 1 indicates full duplex.

Bit(s)	Called	Definition
2-4	Negotiation Status	<p>Indicates the status of link auto-negotiation</p> <p>0 = Auto-negotiation in progress.</p> <p>1 = Auto-negotiation and speed detection failed. Using default values for speed and duplex. Default values are product-dependent; recommended defaults are 10Mbps and half duplex.</p> <p>2 = Auto negotiation failed but detected speed. Duplex was defaulted. Default value is product-dependent; recommended default is half duplex.</p> <p>3 = Successfully negotiated speed and duplex.</p> <p>4 = Auto-negotiation not attempted. Forced speed and duplex.</p>
5	Manual Setting Requires Reset	0 indicates the interface can activate changes to link parameters (auto-negotiate, duplex mode, interface speed) automatically. 1 indicates the device requires a Reset service be issued to its Identity Object in order for the changes to take effect.
6	Local Hardware Fault	0 indicates the interface detects no local hardware fault; 1 indicates a local hardware fault is detected. The meaning of this is product-specific. For example, an AUI/MII interface might detect no transceiver attached, or a radio modem might detect no antenna attached. In contrast to the soft, possibly self-correcting nature of the Link Status being inactive, this is assumed a hard-fault requiring user intervention.
7~31	Reserved.	Shall be set to zero

The Ethernet Link Object Instance supports the following CIP common services:

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute

LLDP Management Object

The LLDP Management Object contains administrative information for the LLDP protocol. Only one instance of the LLDP Management Object shall be implemented. The class code of LLDP Management Object is 0x109.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object. The current value assigned to this value is 1.

Instance Attribute List

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get/Set	LLDP Enable		(Struct.)	
			LLDP Enable Array Length	USINT (16)	Number of bits defined in the LLDP Enable Array member of this structure.
			LLDP Enable Array	Array of BYTE (8)	Bit 0 : Global Enable 0 = LLDP Tx & Rx Disabled 1 = LLDP Tx & Rx Enabled Bit 1-N : Port Tx Enable 0 = LLDP Tx Disabled 1 = LLDP Tx Enabled Bit >N : Reserved Shall be zero and ignored.
2	Get/Set	msgTxInterval		USINT (16)	Message Transmission Interval for LLDP frames. 0 = Reserved 1 - 3600 = Transmit interval (sec.) 3601 - 65535 = Reserved Recommended default value is 30. Note : MOXA real supported transmit interval range is 5-32768.
3	Get/Set	msgTxHold		USINT (8)	Message Transmission Multiplier for LLDP Frames 0 = Reserved 1 - 100 = Transmission Multiplier 101 - 255 = Reserved Recommended default value is 4. Note : MOXA real supported transmit hold time multiplier range is 2-10.

Attr ID	Access Rule	Name	(Struct.)	Data Type	Description
4	Get	LLDP Datastore		WORD (16)	An indication of the retrieval methods for the LLDP database supported by the device. Bit: 0 = LLDP Data Table Object 1 = SNMP 2 = NETCONF YANG 3 = RESTCONF YANG 4 - 15 = Reserved At least one of bits 0 & 1 are required.
5	Get	Last Change		UDINT (32)	The value of sysUpTime taken the last time any entry in the local LLDP database (ignoring TTL) changed.

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute
0x10		✓	Set_Attribute_Single	Used to modify an object instance attribute

LLDP Data Table Object

The LLDP Data Table object displays a record of all adjacent LLDP implementing devices that are currently active according to the receive state machine of the LLDP protocol.

An instance of the LLDP Data Table object shall be implemented per adjacent device detected. Instances shall be created and removed as neighboring devices change. The same instance number should be maintained for each neighboring device until the next power cycle of the device implementing this object.

The class code of the LLDP Data Table Object is 0x10A.

Common Attribute List

Attribute ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this object. The current value is 1.
2	Get	Max Instance	UINT (16)	Maximum instance number of an object currently created in this class level of the device.
3	Get	Number of Instances	UINT (16)	Number of object instances currently created in this class level of the device.
6	Get	Maximum ID Number Class Attributes	UINT (16)	Maximum class attribute ID number implemented in the device.
7	Get	Maximum ID Number Instance Attributes	UINT (16)	Maximum instance attribute ID number implemented in the device.

Instance Attribute

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
1	Get	Ethernet Link Instance Number		UINT (16)	<p>The physical Ethernet port the LLDP frame populating this instance was received on.</p> <p>0 = Unknown</p> <p>1-65535 = Ethernet Link Object (0xF6) Instance Number</p>
2	Get	MAC Address		ETH_MAC_ADDR	<p>The MAC address will be set by the first occurrence of a MAC ID that exists in the following list:</p> <ol style="list-style-type: none"> 1. The CIP MAC Address (TLV Type = 127, Subtype = 2) 2. The Chassis ID (TLV Type = 1) only if subtype = 2 3. The Port ID (TLV Type = 2) only if subtype = 3 4. All zero

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
3	Get	Interface Label		SHORT_STRING	<p>The Interface Label will be a maximum of 64 characters.</p> <p>It is set by the first occurrence of an interface label that exists in the following list:</p> <ol style="list-style-type: none"> 1. The CIP Interface Label (TLV Type = 127, Subtype = 1) 2. The Chassis ID (TLV Type = 1) only if subtype = 6 3. The Port ID (TLV Type = 2) only if subtype = 5 4. A null string
4	Get	Time to Live		UINT (16)	<p>The number of seconds the neighboring information is to be considered valid.</p> <p>0 = Reserved</p> <p>1-65535 = Time To Live (in seconds)</p>
5	Get	System Capabilities TLV		(Struct.)	<p>A structure that contains bitmaps of both the supported and enabled capabilities of the neighboring device.</p>

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
			System Capabilities	WORD (16)	<p>The capabilities which the neighboring device supports based on currently loaded firmware.</p> <p>Bit 0 : Other Bit 1 : Repeater Bit 2 : Bridge Bit 3 : Access Point Bit 4 : Router Bit 5 : Telephone Bit 6 : DOCSIS Cable Device Bit 7 : End Station Bit 8 : C-VLAN component Bit 9 : S-VLAN component Bit 10 : Two-port MAC Relay Component Bit 11-15 : Reserved by IEEE</p> <p>Note : EtherNet/IP Bridged multiport neighboring devices are expected to assert high bits 0 & 2.</p>

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
			Enabled Capabilities	WORD (16)	<p>The capabilities currently enabled on the neighboring device.</p> <p>Bit 0 : Other Bit 1 : Repeater Bit 2 : Bridge Bit 3 : Access Point Bit 4 : Router Bit 5 : Telephone Bit 6 : DOCSIS Cable Device Bit 7 : End Station Bit 8 : C-VLAN component Bit 9 : S-VLAN component Bit 10 : Two-port MAC Relay Component Bit 11-15 : Reserved by IEEE</p> <p>Note :</p> <p>EtherNet/IP Bridged multiport neighboring devices are expected to assert high bits 0 & 2.</p>
6	Get	IPv4 Management Address		(Struct.)	The IPv4 management addresses of the neighboring device.
			Management Address Count	USINT	0-255 = Number of received Management Address TLV's from this neighbor.
			Management Address	ARRAY of UDINT (32)	<p>The IP address shall be set to a valid Class A, B, or C address.</p> <p>And shall not be set to all zeros or the loopback address (127.0.0.1).</p>
7	Get	CIP Identification		(Struct.)	<p>The CIP Identification TLV of the neighboring device, if present.</p> <p>Set by the CIP Identification TLV (TLV Type = 127, Subtype = 09), if present. Otherwise 0</p>
			Vendor ID	UINT (16)	Vendor ID

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
			Device Type	UINT (16)	Device Type
			Product Code	UINT (16)	Product Code
			Major Revision	BYTE (8)	Major Revision
			Minor Revision	USINT (8)	Minor Revision
			CIP Serial Number	UDINT (32)	Serial Number – Shall not be zero 0.
8	Get	Additional Ethernet Capabilities		(Struct.)	A TLV for Ethernet Preemption Support from the neighboring device. Set by the Additional Ethernet Capabilities TLV (TLV type = 127, Subtype 7), if present. Otherwise, 0.
			Preemption Support	BOOL (8)	Allows a link partner to know if preemption is supported on the link. 0 = Not Supported 1 = Supported
			Preemption Status	BOOL (8)	Allows a link partner to know if preemption is enabled on the link. 0 = Not Enabled 1 = Enabled
			Preemption Active	BOOL (8)	Allows a link partner to know if link preemption has passed embedded verification. 0 = Not Active 1 = Active

Attribute ID	Access Rule	Name	(Struct.)	Data Type	Description
			Additional Fragment Size	USINT (8)	The number of octets that must be transmitted of a frame before preemption occur. 0 = 64 octets 1 = 128 octets 2 = 192 octets 3 = 256 octets 4-255 = Reserved
9	Get	Last Change		UDINT (32)	The value of sysUpTime taken the last time any attribute in this instance changed.

Common Service

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x01	✓		Get_Attribute_All	Returns the contents of all attributes of the class.
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x11	✓		Find_Next_Object_Instance	Causes the specified Class to search for and return a list of instances ID's of existing instances of the LLDP Data Table Object.

Moxa Networking Object (Vendor Specific)

The Moxa Networking object includes system information and status.

It can also be used to do the device diagnostic & configuration through explicit messaging.

The class code is **0x404**.

Class Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	Revision	UINT (16)	Revision of this objec

Instance Attribute List

Attr ID	Access Rule	Name	Data Type	Description
1	Get	CPU Usage	USINT (8)	Percentage of CPU usage (0 to100)
2	Get	L2 Redundancy	USINT (8)	Bit mask of device roles. Bit 0: RSTP 0 = RSTP Disabled 1 = RSTP Enabled Bit 1: MSTP 0 = MSTP Disabled 1 = MSTP Enabled Bit 2: Turbo Chain 0 = Turbo Chain Disabled 1 = Turbo Chain Enabled Bit 3: Turbo Ring v2 0 = Turbo Ring v2 Disabled 1 = Turbo Ring v2 Enabled Bit 4: Dual-Homing 0 = Dual-Homing Disabled 1 = Dual-Homing Enabled Bit 5: MRP 0 = MRP Disabled 1 = MRP Enabled

Attr ID	Access Rule	Name	Data Type	Description
3	Get	Relay Alarm Status	USINT (8)	<p>Relay alarm event-triggered status.</p> <p>When Relay alarm is triggered, value will change from 0x0 to 0x1.</p> <p>Bit 0: Relay (MGMT-Relay) alarm status 0 = Alarm doesn't trigger. 1 = Alarm triggered.</p> <p>Bit 1: PWR1-Relay alarm status 0 = Alarm doesn't trigger. 1 = Alarm triggered.</p> <p>Bit 2: PWR2-Relay alarm status 0 = Alarm doesn't trigger. 1 = Alarm triggered.</p>
4	Get/Set	Cold Start	USINT (8)	<p>System cold start event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
5	Get/Set	Warm Start	USINT (8)	<p>System warm start event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>
6	Get/Set	Redundant port health check fail	USINT (8)	<p>Redundant port health check fail.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
7	Get/Set	PD over current	USINT (8)	<p>Current of port has exceeded the safety limit. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>
8	Get/Set	PD no response	USINT (8)	<p>The device connected to this port is not responding to the PD failure check. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
9	Get/Set	Power On	USINT (8)	<p>Power supply on event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>
10	Get/Set	Power Off	USINT (8)	<p>Power supply off event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
11	Get/Set	DI on	USINT (8)	<p>Digital input on event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>
12	Get/Set	DI off	USINT (8)	<p>Digital input off event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
13	Get/Set	Port On	USINT (8)	<p>Port link up event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>
14	Get/Set	Port Off	USINT (8)	<p>Port link down event notification.</p> <p>(Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable.</p> <p>0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
15	Get/Set	Port shutdown by Port Security	USINT (8)	<p>Port shutdown by Port Security event notification. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>
16	Get/Set	Port shutdown by Rate Limit	USINT (8)	<p>Port shutdown by Rate Limit event notification. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
17	Get/Set	Port recovered by Rate Limit	USINT (8)	<p>Port recovered by Rate Limit event notification. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>
18	Get/Set	Fiber Check Warning	USINT (8)	<p>Fiber check warning event notification. (Bit 1 should call MGMT-Relay if device support more than 1 relay. Bit 2-3 depends on device supported relay number.)</p> <p>Bit 0: Event notification enable. 0 = Disabled 1 = Enabled</p> <p>Bit 1: Relay (MGMT-Relay) alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 2: PWR1-Relay alarm enable. 0 = Disabled 1 = Enabled</p> <p>Bit 3: PWR2-Relay alarm enable. 0 = Disabled 1 = Enabled</p>

Attr ID	Access Rule	Name	Data Type	Description
19	Set	Relay Alarm Cut-off	USINT (8)	<p>Cut off the relay alarm.</p> <p>(Bit 0 should call MGMT-Relay if device support more than 1 relay. Bit 1-2 depends on device supported relay number.)</p> <p>Bit 0: Relay (MGMT-Relay)</p> <p>0 = Don't cut-off relay</p> <p>1 = Cut-off relay</p> <p>Bit 1: PWR1-Relay</p> <p>0 = Don't cut-off relay</p> <p>1 = Cut-off relay</p> <p>Bit 2: PWR2-Relay</p> <p>0 = Don't cut-off relay</p> <p>1 = Cut-off relay</p>
20	Set	Reset MIB Count	USINT (8)	<p>Reset port MIB counters. (Ethernet Link object's attributes 4-5 and 12-13.)</p> <p>Any value indicates to reset port MIB counter.</p>
21	Set	Reset Device	USINT (8)	<p>Reboot and reset to default</p> <p>0 = Reserved.</p> <p>1 = Reboot the device</p> <p>2 = Reset to default</p>

Common Service List

Service Code	Implementation Class	Implementation Instance	Service Name	Description
0x0E	✓	✓	Get_Attribute_Single	Used to read an object instance attribute.
0x10	✓		Set_Attribute_Single	Used to modify an object instance attribute

Configuration Types

This table describes the different types of configurations that your device uses.

Configuration Type	Description
Startup Config	The configuration that is loaded when the device boots up. These settings persist even when the device is powered off.
Running Config	<p>The configuration that is currently in use by the device.</p> <ul style="list-style-type: none">• If auto-save is enabled, all changes will be saved to the startup config, and will be retained when the device powers off.• If auto-save is disabled, any unsaved changes will be lost when the device powers off. <p>Refer to Disable/Enable Auto Save for more information.</p>
Factory Default Config	The pre-defined factory default configuration of your device. This configuration cannot be changed.

Event Log Descriptions

This table describes the different events that can be recorded in the event log files.

Event Name	Severity	Event Description
802.1X Auth Failed	Warning	802.1x authentication failed on port {{index}}/{{number}} with {{buffer}}
ABC-02 is inserted or unplugged	Notice	ABC-02 is {{inserted/unplugged}}.
ABC-03 is inserted or unplugged	Notice	ABC-03 is {{inserted/unplugged}}.
Account log out	Notice	[Account:{{user_name}}] logged out.
Account removed	Notice	[Account:{{user_name}}] has been removed by admin.
Account settings changed	Notice	Account settings of [Account:{{user_name}}] has been updated. Account settings of [Account:{{user_name}}] has been deleted. Account settings of [Account:{{user_name}}] has been created.
Announce message with different interval	Warning	An Announce message with a different interval has been received from port {{index}}/{{number}}
Announce timeout	Warning	PTP port {{index}}/{{number}} Announce receipt timer has timed out.
Check if hardware revision is valid	Notice	The hardware revision of Power Module {{index}} is not allowed.
Check if it is a known power module	Warning	To avoid potential overheating, Moxa does not recommend using a {{index}} power supply with this device.
Cold start	Critical	System has performed a cold start.
Configuration changed	Notice	Configuration {{modules}} changed by {{username}}.
Configuration exported	Notice	Configurations exported {{successful /failed}} by {{username}} via {{method}}.
Configuration imported	Notice	Configuration import {{successful /failed}} by {{username}} via {{method}}.
Coupling changed	Warning	Turbo Ring v2 coupling path status has changed.

Event Name	Severity	Event Description
DHCP client ingress discards packets due to the DHCP Snooping rule	Warning	VLAN <vlan-id> dropped DHCP client ingress packets due to a violation of the DHCP Snooping rule. Total packets discarded: <number>
DHCP server discards packets due to the DHCP Snooping rule	Warning	VLAN <vlan-id> dropped DHCP server packets due to a violation of the DHCP Snooping rule. Total packets discarded: <number>
DI off	Notice	Digital Input {{index}} has been turned off.
DI on	Notice	Digital Input {{index}} has been turned on.
Dual homing path changed	Warning	Dual Homing path has switched.
Event log export	Notice	Event Log export {{successful /failed}} by {{username}} via {{method}}.
Failed to overwrite the dhcpsnp static entry	Warning	Static entry: VLAN: {{Vlan Id}}, MAC: {{mac addr}} already exists.
Fiber Check warning	Warning	Port {{index}}/{{number}} 's temperature has exceeded the threshold. Port{{index}}/{{number}} Tx power is over the threshold. Port{{index}}/{{number}} Tx power is under the threshold. Port{{index}}/{{number}} Rx power is over the threshold. Port{{index}}/{{number}} Rx power is under the threshold.
Firmware upgrade failed	Warning	Firmware failed to upgrade.
Firmware upgrade successful	Notice	Firmware successfully upgraded.
Grand Master changed	Warning	The PTP grandmaster has changed from {{mac addr}} to {{mac addr}}
Hardware revision is not allowed	Error	The hardware revision of Line Module %d is not allowed.
Interface link down	Notice	Interface{{number}} down.
Interface link up	Notice	Interface {{number}} up.

Event Name	Severity	Event Description
Issue event log to syslog server	Emergency	The system has lost power.
LLDP table changed	Info	LLDP remote table has changed.
Log capacity threshold	Warning	Number of event log entries <code>{{logEntryNum}}</code> has reached the threshold.
Log Turbo Chain Port Restart	Notice	Port-Channel <code>{{channel id}}</code> has restarted by Turbo Chain. Port <code>{{index}}/{{number}}</code> has restarted by Turbo Chain.
Login failed	Warning	[Account <code>{{user_name}}</code>] log in failed via <code>{{interface}}</code> .
Login lockout	Warning	[Account <code>{{user_name}}</code>] locked due to <code>{{failed_times}}</code> failed login attempts.
Login successful	Notice	[Account <code>{{user_name}}</code>] successfully logged in via <code>{{interface}}</code> .
Low input voltage	Warning	The input voltage of the power supply has dropped below 46 VDC. Please adjust the voltage to between 46 and 57 VDC to fit the PoE voltage requirement.
Master changed	Warning	Ring <code>{{Index}}</code> master has changed.
Master mismatch	Warning	Ring <code>{{Index}}</code> master setting does not match.
Module change	Notice	M <code>{{index}}</code> module has changed.
Module Initialized Fail	Error	M <code>{{index}}</code> Module initialized has failed.
Module inserted	Notice	M <code>{{Index}}</code> Module inserted.
Module removed	Notice	M <code>{{index}}</code> Module removed.
MSTP new port role	Warning	MSTP (MST <code>{{Index}}</code>) port <code>{{number}}</code> role changed from <code>{{role}}</code> to <code>{{role}}</code> .
MSTP root changed	Warning	MSTP (MST <code>{{Index}}</code>) new root has been elected in topology.
MSTP topology changed	Warning	Topology (MST <code>{{Index}}</code>) has been changed by MSTP.
OSPF DR router adjacency changed	Notice	Interface <code>{{ip addr}} {{ip addr}} {{ip addr}} {{ip addr}}</code> DR neighbor <code>{{ip addr}} {{ip addr}} {{ip addr}} {{ip addr}}</code> adjacency changed.

Event Name	Severity	Event Description
OSPF interface DR changed	Notice	Interface {{ip addr}}-{{ip addr}}-{{ip addr}}-{{ip addr}} DR Change-{{ip addr}}-{{ip addr}}-{{ip addr}}-{{ip addr}} to {{ip addr}}-{{ip addr}}-{{ip addr}}-{{ip addr}}.
OSPF interface ISM became DR	Notice	Interface {{ip addr}}-{{ip addr}}-{{ip addr}}-{{ip addr}} become DR.
Packet dropped by Port Security	Warning	Port {{index}}/{{number}} dropped packets due to violation of Port Security rule.
Password changed	Notice	Password of [Account: {{user_name}}] has been changed.
PD no response	Error	Port {{number}} device is not responding to the PD failure check. Please check the device status.
PD over-current	Error	Current of port {{number}} has exceeded the safety limit. Please check the device status.
PD power off	Notice	Port {{number}} PD power off.
PD power on	Notice	Port {{number}} PD power on.
Port Link Down	Notice	Port {{index}}/{{number}} link down. Port-channel {{Channel id}} link down.
Port Link Up	Notice	Port {{index}}/{{number}} link up. Port-channel {{Channel id}} link up.
Port recovery by Rate Limit	Warning	Port {{index}}/{{number}} has recovered by rate limit.
Port shutdown by Loop	Critical	Port {{index}}/{{number}} looping and shutdown.
Port shutdown by Port Security	Warning	Port {{index}}/{{number}} has shut down due to a violation of the Port Security rule.
Port shutdown by Rate Limit	Warning	Port {{index}}/{{number}} has excessive traffic and shutdown.
Port state change	Info	PTP port {{index}}/{{number}} has changed from {{state}} to {{state}}.
Power budget exceeded	Warning	The consumed power {{power_value}} of all the PDs have exceeded the maximum input power {{input_power_value}}.

Event Name	Severity	Event Description
Power detection failure	Warning	Port {{number}} device is {{Not present/Legacy PD/802.3 af/802.3 at/802.3 bt/NIC/Unknown}}. Please {{No suggestion/enable PoE power output/disable PoE power output/select PoE output mode to High power/select PoE output mode to Force/enable legacy PD detection/raise external power supply voltage greater than 46 VDC}}.
Power module inserted	Notice	Power Module {{index}} has been inserted.
Power module removed	Notice	Power Module {{index}} has been removed.
Power Off->On	Notice	Power {{index}} has turned off.
Power On->Off	Notice	Power {{index}} has turned on.
PTP message with the wrong domain number	Warning	The PTP message with the wrong domain number was received from port {{index}}/{{number}}.
Redundant port health check failed	Error	Redundant port {{index}}/{{number}} health check fail.
Relay Override message	Notice	{{relay_name}} relay alarm has been cut off.
Relay Triggered message	Notice	{{MGMT/PWR1/PWR2}} alarm is on due to {{Event Name}}.
Resource log export	Notice	Resource Log export {{successful/failed}} by {{username}} via {{method}}.
RMON failing alarm	Warning	{{user defined}}.
RMON raising alarm	Warning	{{user defined}}.
RSTP invalid BPDU	Warning	RSTP Port-Channel {{channel id}} received an invalid BPDU (type: {{type}}, value: {{value}}). RSTP port {{index}}/{{number}} received an invalid BPDU (type: {{type}}, value: {{value}}).
RSTP migration	Warning	Port-Channel {{channel id}} changed to {{rstp/stp}}. Port {{index}}/{{number}} changed to {{rstp/stp}}.

Event Name	Severity	Event Description
RSTP new port role	Warning	RSTP Port-Channel {{channel id}} role changed from {{role}} to {{role}}. RSTP port {{index}}/{{number}} role changed from {{role}} to {{role}}.
RSTP root changed	Warning	RSTP new root has been elected in topology.
RSTP topology changed	Warning	Topology has been changed by RSTP.
Send message failed	Warning	PTP port {{index}}/{{number}} failed to transmit {{Type}}.
SSH Key generated	Notice	SSH key has been regenerated.
SSL certification changed	Notice	SSL certificate has been changed. SSL certificate has been regenerated.
Sync status changed	Warning	The PTP sync status has changed from {{PreSyncStatus}} to {{CurSyncStatus}}.
Topology changed (MRP)	Warning	Topology change has been detected, MRP {{strMRMState}}.
Topology changed (MSTP)	Warning	Topology (MST{{Index}}) has been changed by MSTP.
Topology changed (RSTP)	Warning	Topology has been changed by RSTP.
Topology changed (Turbo Chain)	Warning	Topology has been changed by Turbo Chain.
Topology changed (Turbo Ring)	Warning	Topology change has been detected on Ring {{RingIndex}} of Turbo Ring v2.
Trust host moved from one port to another port (Port Security)	Warning	A trust host, MAC is {{mac address}} with VLAN {{Vlan Id}}, moved from port {{index}}/{{number}} to port {{index}}/{{number}}.
Unknown module	Warning	Module {{index}} Unknown Module Initialized Failed.
Warm start	Notice	System has performed a warm start.

Fiber Check Threshold Values for Auto Mode

This table shows the default thresholds for temperature, Tx power, and Rx power for Moxa fiber modules.

Module	Temperature Threshold (°C)	Tx Power Low Threshold (dBm)	Tx Power High Threshold (dBm)	Rx Power Low Threshold (dBm)	Rx Power High Threshold (dBm)
FEMST	120	-20	-14	-32.0	-3.0
FEMSC	120	-20	-14	-32.0	-3.0
FESSC	120	-5.0	0.0	-34.0	-3.0
SFP-1FEMLC-T	120	-18.0	-8.0	-32.0	-3.0
SFP-1FESLC-T	120	-5.0	0.0	-34.0	-3.0
SFP-1FELLC-T	120	-5.0	0.0	-34.0	-3.0
SFP-1GSXLC-T	110	-9.5	-4.0	-18.0	0.0
SFP-1GLSXC-T	120	-9.0	-1.0	-19.0	-1.0
SFP-1GLXLC-T	120	-9.0	-3.0	-21.0	-3.0
SFP-1GLHLC-T	120	-8.0	-3.0	-23.0	-3.0
SFP-1GLHXLC-T	120	-4.0	3.0	-24.0	-1.0
SFP-1GZXLC-T	120	0.0	5.0	-24.0	-1.0
SFP-1G10ALC-T	120	-9.0	-3.0	-21.0	-3.0

Module	Temperature Threshold (°C)	Tx Power Low Threshold (dBm)	Tx Power High Threshold (dBm)	Rx Power Low Threshold (dBm)	Rx Power High Threshold (dBm)
SFP-1G10BLC-T	120	-9.0	-3.0	-21.0	-3.0
SFP-1G20ALC-T	120	-8.0	-2.0	-23.0	-2.0
SFP-1G20BLC-T	120	-8.0	-2.0	-23.0	-2.0
SFP-1G40ALC-T	120	-3.0	2.0	-23.0	-1.0
SFP-1G40BLC-T	120	-3.0	2.0	-23.0	-1.0
SFP-1GSXLC	100	-9.5	-4.0	-18.0	0
SFP-1GLSXLC	100	-9.0	-1.0	-19.0	-1.0
SFP-1GLXLC	100	-9.0	-3.0	-21.0	-3.0
SFP-1GLHLC	100	-8.0	-3.0	-23.0	-3.0

SFP-10GSRLC-T	110	-5.0	-1.0	-9.9	0.5

Modbus Data Map and Information

The data map addresses of Moxa switches shown in the following tables start from MODBUS address 30001 for Function Code 4. For example, the address offset 0x0000 (hex) equals MODBUS address 30001, and the address offset 0x0010 (hex) equals MODBUS address 30017. Note that all the information read from Moxa switches are in hex mode. To interpret the information, refer to the ASCII table for the translation (For example, 0x4D = 'M', 0x6F = 'o').

System Information

Address Offset	Data type	Interpretation	Description
0x0000	1 word	HEX	Vendor ID = 0x1393
0x0001	1 word		Unit ID (Ethernet = 1)
0x0002	2 word	HEX	Product Code (Please refer to Product Code Table)
0x0010	20 words	ASCII	Vendor Name Ex: Vendor Name = "Moxa" Word 0 Hi byte = 'M' Word 0 Lo byte = 'o' Word 1 Hi byte = 'x' Word 1 Lo byte = 'a' Word 2 Hi byte = '\0' Word 2 Lo byte = '\0'

Address Offset	Data type	Interpretation	Description
0x0030	20 words	ASCII	Product Model EX: Product Model = "MDS-G4028" Word 0 Hi byte = 'M' Word 0 Lo byte = 'D' Word 1 Hi byte = 'S' Word 1 Lo byte = '-' Word 2 Hi byte = 'G' Word 2 Lo byte = '4' Word 3 Hi byte = '0' Word 3 Lo byte = '2' Word 3 Hi byte = '8' Word 4 Lo byte = '\0'
0x004B	6 words	ASCII	Product Serial Number
0x0051	2 words	HEX	Firmware Version Word 0 Hi byte = major (A) Word 0 Lo byte = minor (B) Word 1 Hi byte = release (C) Word 1 Lo byte = build (D)
0x0053	2 words	HEX	Firmware Build Date For example: Word 0 = 0 x 0609 Word 1 = 0 x 0705 Firmware was built on 2007-05-06 at 09 o'clock
0x0055	3 words	HEX	Ethernet MAC Address Ex: MAC = 00-01-02-03-04-05 Word 0 Hi byte = 0 x 00 Word 0 Lo byte = 0 x 01 Word 1 Hi byte = 0 x 02 Word 1 Lo byte = 0 x 03 Word 2 Hi byte = 0 x 0 Word 2 Lo byte = 0 x 05
0x0058	1 word	HEX	Power 1 0x0000: Off 0x0001: ON

Address Offset	Data type	Interpretation	Description
0x0059	1 word	HEX	Power 2 0x0000: Off 0x0001: On
0x005A	1 word	HEX	Fault LED Status 0x0000: No 0x0001: Yes
0x0080	1 word	HEX	DI1 0x0000:Off 0x0001:On 0xFFFE: DI1 is Not Supported
0x0081	1 word	HEX	DI2 0x0000:Off 0x0001:On 0xFFFE: DI2 is Not Supported
0x0082	1 word	HEX	DO1 0x0000:Off 0x0001:On 0xFFFE: DO1 is Not Supported
0x0083	1 word	HEX	DO2 0x0000:Off 0x0001:On 0xFFFE: DO2 is Not Supported
0x0084	1 word	HEX	DO3 0x0000:Off 0x0001:On 0xFFFE: DO3 is Not Supported
0x0085 (Power Module 1) 0x0086 (Power Module 2)	1 word	HEX	Power Module Present 0x0000: Not Present 0x0001: Present 0xFFFE: Power Module is Not Supported

Address Offset	Data type	Interpretation	Description
0x0087 (Power Module 1) 0x0097 (Power Module 2)	16 words	ASCII	Power Module Name EX: "PWR-HV-P48" Word 0 Hi byte = 'P' Word 0 Lo byte = 'W' Word 1 Hi byte = 'R' Word 1 Lo byte = '-' Word 2 Hi byte = 'H' Word 2 Lo byte = 'V' Word 3 Hi byte = '-' Word 3 Lo byte = 'P' Word 4 Hi byte = '4' Word 4 Lo byte = '8' Word 5 Hi byte = '\n' Word 5 Lo byte = '\n'
0x00A7 (Power Module 1) 0x00AD (Power Module 2)	6 words	ASCII	Power Module Serial Number
0x00B3 (Power Module 1) 0x00B5 (Power Module 2)	2 words	HEX	Power Module Product Revision Word 0 Hi byte = major (A) Word 0 Lo byte = subversion (B) Word 1 Hi byte = minor (C) Word 1 Lo byte = 0
0x00B7 (External Module 1) 0x00B8 (External Module 2) ...	1 word	HEX	External Module Present 0x0000: Not Present 0x0001: Present 0xFFFF: External Module is Not Supported

Port Information

Address Offset	Data type	Interpretation	Description
0x1000 (Port 1)	1 word	HEX	Port Status
0x1001 (Port 2)			0x0000: Link down
...			0x0001: Link up
Maximum Port (n)			0x0002: Disable
0x1000 + n (Channel Group 1)			0xFFFF: No port
0x1000 + n + 1 (Channel Group 2)			
...			
0x1100 (Port 1)	1 word	HEX	Port Speed (Y: Channel group active port count)
0x1101 (Port 2)			0x0000: 10M-Half
...			0xY001: 10M-Full
Maximum Port (n)			0x0002: 100M-Half
0x1100 + n (Channel Group 1)			0xY003: 100M-Full
0x1100 + n + 1 (Channel Group 2)			0xY004: 1G-Full
...			0xY005: 2500M-Full
			0xY006: 10G-Full
			0xY007: 40G-Full
			0xY008: 50G-Full
	0xY009: 25G-Full		
	0xY00A: 100G-Full		
	0xFFFE: Inactive Link		
	0xFFFF: No port		
0x1200 (Port 1)	1 word	HEX	Port Flow Ctrl
0x1201 (Port 2)			0x0000:Off
...			0x0001:On
Maximum Port (n)			0xFFFE: Inactive Link
			0xFFFF:No port

Address Offset	Data type	Interpretation	Description
0x1300 (Port 1)	1 word	HEX	Port MDI/MDIX
0x1301 (Port 2)			0x0000: MDI
...			0x0001: MDIX
Maximum Port (n)			0xFFFF: Fiber Port
			0xFFFE: Inactive Link
			0xFFFF: No port
0x1400 (Port 1)	32 words	ASCII	Port Media Type
0x1420 (Port 2)			Ex: Port 1 Media Type = "100TX,RJ45."
...			Word 0 Hi byte = '1'
Maximum Port (n)			Word 0 Lo byte = '0'
			Word 1 Hi byte = '0'
			Word 1 Lo byte = 'T'
			...
	Word 4 Hi byte = '4'		
	Word 4 Lo byte = '5'		
	Word 5 Hi byte = '\'		
	Word 5 Lo byte = '\0'		

Packet Information

Address Offset	Data type	Interpretation	Description
0x2000 (Port 1)	2 words	HEX	Port Tx Packets
0x2002 (Port 2)			Ex: port 1 Tx Packet Amount = 44332211
...			Received MODBUS response: 0x02A474B3
Maximum Port (n)			Word 0 = 0x02A4
0x2000 + (n * 2) (Channel Group 1)			Word 1 = 0x74B3
0x2000 + ((n + 1) * 2) (Channel Group 2)			
...			

Address Offset	Data type	Interpretation	Description
0x2100 (Port 1)	2 words	HEX	Port Rx Packets
0x2102 (Port 2)			Ex: port 1 Tx Packet Amount = 44332211
...			
Maximum Port (n)			Received MODBUS response: 0x02A474B3
0x2100 + (n * 2) (Channel Group 1)			Word 0 = 0x02A4
0x2100 + ((n + 1) * 2) (Channel Group 2)			Word 1 = 0x74B3
...			
0x2200 (Port 1)	2 words	HEX	Port Tx Error Packets
0x2202 (Port 2)			Ex: port 1 Tx Packet Amount = 44332211
...			
Maximum Port (n)			Received MODBUS response: 0x02A474B3
0x2200 + (n * 2) (Channel Group 1)			Word 0 = 0x02A4
0x2200 + ((n + 1) * 2) (Channel Group 2)			Word 1 = 0x74B3
...			
0x2300 (Port 1)	2 words	HEX	Port Rx Error Packets
0x2302 (Port 2)			Ex: port 1 Tx Packet Amount = 44332211
...			
Maximum Port (n)			Received MODBUS response: 0x02A474B3
0x2300 + (n * 2) (Channel Group 1)			Word 0 = 0x02A4
0x2300 + ((n + 1) * 2) (Channel Group 2)			Word 1 = 0x74B3
...			

Redundancy Information

Address Offset	Data type	Interpretation	Description
0x3000	1 word	HEX	Redundancy Protocol 0x0000: None 0x0001: RSTP 0x0002: Turbo Ring V2 0x0003: Turbo Chain 0x0004: Dual Homing 0x0005: RSTP & Dual Homing 0x0006: Turbo Ring V2 & Dual Homing 0x0007: Turbo Chain & Dual Homing

Product Codes Used in Industrial Protocols

The following table contains Moxa product codes used in industrial protocols.

Product name	Product code (16-bit)	Product code (32-bit)
EDS-4008	0x1100	0x11021000
EDS-4008-2GT-2GS	0x1104	0x11021004
EDS-4008-2MSC	0x1101	0x11021001
EDS-4008-2MST	0x1102	0x11021002
EDS-4008-2SSC	0x1103	0x11021003
EDS-4008-4P-2GT-GS	0x1105	0x11024005
EDS-4009-3MSC	0x1107	0x11022007
EDS-4009-3MST	0x1108	0x11022008
EDS-4009-3SSC	0x1109	0x11022009
EDS-4012-4GC	0x110B	0x1102300b
EDS-4012-4GC-HV-T	0x110D	0x1102300d
EDS-4012-4GS	0x110A	0x1102300a
EDS-4012-4GS-HV-T	0x110C	0x1102300c
EDS-4012-8P-4GS	0x110E	0x1102340e
EDS-4014-4GS-2QGS-HV-T	0x1112	0x11024012
EDS-G4008	0x1106	0x11021806

Security Guidelines

This appendix explains security practices for installing, operating, maintaining, and decommissioning this device. We strongly recommend you follow these guidelines to enhance network and equipment security.

Physical Installation

1. This device must be installed in an access controlled area, where only the necessary personnel have physical access to the device.
2. This device must not be directly connected to the Internet, which means switches must be installed within a security perimeter, which can be implemented by a firewall at the border since this device is not classified as zone/boundary equipment
3. Please follow the instructions in the Quick Installation Guide, which is included in the package, to ensure you install this device correctly in your environment.
4. This device has anti-tamper labels on the enclosures. This allows an administrator to tell whether the device has been tampered with.
5. Ports that are not in use should be deactivated. Please refer to Port Interface for more information.

Account Management

Follow these best practices when setting up an account.

1. Each account should be assigned the correct privileges: Only allow the minimum number of people necessary to have admin privileges so they can perform device configuration or modifications, while other users should only have read access privileges. This device supports both local accounts and remote centralized mechanisms for authentication, including RADIUS and TACACS+.
2. Change the default password, and strengthen the account password complexity by:
 - a. Enabling the Password Policy function.

- b. Increasing the minimum password length to at least eight characters.
 - c. Defining a password policy to ensure that passwords contain at least an uppercase and lowercase letter, a digit, and a special character.
 - d. Setting user passwords to expire after a certain period of time.
3. Enforce regulations that ensure that only a trusted host can access this device. Please refer to [Trusted Access](#) for more information.

Vulnerable Network Ports

1. For network security concerns, we strongly recommend that you change the port numbers—such as TCP port numbers for HTTP, HTTPS, Telnet, and SSH—for the protocols that are in use. Ports that are not in use but are still reachable create a security risk and should be disabled. Refer to [Management Interface](#) for more information.
2. In order to avoid eavesdroppers from snooping confidential information, users should adopt encryption-based communication protocols, such as HTTPS instead of HTTP, SSH instead of Telnet, SFTP instead of TFTP, SNMPv3 instead of SNMPv1/v2c, etc. In addition, the maximum number of sessions should be kept to an absolute minimum. Refer to [Management Interface](#) for more information.
3. Users should regenerate SSL certificate and SSH key for this device before commissioning HTTPS or SSH applications. Refer to [SSH & SSL](#) for more information.

Operation

1. In order to ensure that communications are properly protected, use a strong cryptographic algorithm for key exchange or encryption protocols for HTTPS/SSH applications. This device follows the NIST SP800-52 and SP800-131 standards, and supports TLS v1.2 and v1.3 with the following cipher suites:
 - a. **TLS v1.2**

Cipher suite name	Key exchange	Authentication	Encryption	Hash function
TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256	ECDHE	RSA	CHACHA20-POLY1305	SHA256
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256	ECDHE	ECDSA	AES128	SHA256
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	ECDHE	RSA	AES128	SHA256
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	ECDHE	RSA	AES256	SHA384
TLS_DHE_RSA_WITH_AES_128_GCM_SHA256	Ephemeral DH	RSA	AES128	SHA256
TLS_DHE_RSA_WITH_AES_256_GCM_SHA384	Ephemeral DH	RSA	AES256	SHA384
TLS_DHE_RSA_WITH_CHACHA20_POLY1305_SHA256	Ephemeral DH	RSA	CHACHA20-POLY1305	SHA256
TLS_ECDHE-RSA_WITH_AES256-SHA384	ECDHE	RSA	AES256	SHA384
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	ECDHE	RSA	AES128	SHA256
TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256	ECDHE	ECDSA	CHACHA20-POLY1305	SHA256
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	ECDHE	RSA	AES256	SHA384
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384	ECDHE	ECDSA	AES256	SHA384
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256	ECDHE	ECDSA	AES128	SHA256

b. TLS V1.3

Cipher suite name	Key exchange	Encryption	Mode	Hash function
TLS_AES_256_GCM_SHA384	any	AES256	GCM	SHA384
TLS_CHACHA20_POLY1305_SHA256	any	CHACHA20-POLY1305	N/A	SHA256
TLS_AES_128_GCM_SHA256	any	AES128	GCM	SHA256

2. Below is a list of the recommended secure browsers that support TLS v1.2 or higher:

Browser	Version
Microsoft Edge	All
Microsoft Internet Explorer	v11 or above
Mozilla Firefox	v27 or above
Google Chrome	v38 or above
Apple Safari	v7 or above

Reference: <https://support.globalsign.com/ssl/general-ssl/tls-protocol-compatibility#Browsers>

3. This device supports event logs and syslog for SIEM integration:
 - a. **Event log:** Due to limited storage capacity, the event log can only accommodate a maximum of 10,000 entries. Administrators can set a warning for a pre-defined threshold. We recommend that users regularly back up system event logs. Please refer to [Event Logs](#) for more information.
 - b. **Syslog:** this device supports syslog, and advanced secure TLS-based syslog for centralized SIEM integration. Please refer to [Syslog](#) for more information.
4. This device can provide information for control system inventory:
 - a. **SNMPv1, v2c, v3:** We recommend administrators use SNMPv3 with authentication and encryption to manage the network. Please refer to the MIB file for more information.
 - b. **Telnet/SSH:** We recommend that administrators use SSH with authentication and encryption to retrieve device properties.
 - c. **HTTP/HTTPS:** We recommend that administrators use HTTPS with a certificate

that has been granted by a Certificate Authority to configure this device.

d. **MMS:** We recommend administrators enable MMS security mode to enhance protection.

5. **Denial of Service protection:** To avoid disruption of normal operation of the switch, administrators should configure the QoS function. This device supports ingress rate limit and egress shaper. Administrators can decide how to deal with excess data flow and configure the device accordingly. This process will regulate the resulted data rate per port. Please refer to **QoS** for more information.
6. **Time synchronization with authentication:** Time synchronization is crucial for process control. To prevent malicious attacks whereby the settings are changed without permission, authentication must be in place between the NTP server and client. This device supports NTP with a pre-shared key. Please refer to **NTP** for more information.
7. **Periodically regenerate the SSH and SSL certificates:** Even though this device supports RSA 2048-bit and SHA-256 to ensure sufficient complexity, we strongly recommend that users frequently renew their SSH key and SSL certificate in case the key is compromised. Please refer to **SSH & SSL** for more information.
8. Below is the list of the protocol port numbers used for all external interfaces.

a. **Protocol:TCP**

Service Type	Port Number	Default state	Port can be modified
SSH	22	Enabled	Y
Telnet	23	Disabled	Y
E-Mail Server (SMTP)	25	Disabled	Y
TACACS+	49	Disabled	Y
HTTP	80	Enabled	Y
MMS	102	Disabled	N
HTTPS	443	Enabled	Y
Moxa Service	443	Enabled	N
Modbus	502	Disabled	N

Service Type	Port Number	Default state	Port can be modified
Ethernet/IP	44818	Disabled	N

b. Protocol: UDP

Service Type	Port Number	Default state	Port can be modified
DHCP Server	67	Disabled	N
NTP	123	Disabled	N
SNMP	161	Disabled	Y
PTP (IP based)	319/320	Disabled	N
Syslog	514	Disabled	Y
RADIUS	1812	Disabled	Y
Ethernet/IP	2222	Disabled	N
PROFINET	34964/49152	Disabled	N
Moxa Service	40404	Enabled	N

Maintenance

1. Perform firmware upgrades frequently to enhance features, deploy security patches, or fix bugs.
2. Frequently back up the system configurations. In order to properly protect the system configuration files from being tampered with, this device supports password encryption and signature authentication for backup files.
3. Examine event logs frequently to detect any anomalies.
4. To report vulnerabilities of Moxa products, please submit your findings on the following web page: <https://www.moxa.com/en/support/product-support/security-advisory/report-a-vulnerability>

Decommissioning

To avoid disclosing sensitive information such as account passwords and certificates, please reset the system settings to factory default before decommissioning this device or sending it back to Moxa RMA service.

Severity Level List

This is a list of severity levels and descriptions, which are based on CVSS vulnerability classifications.

Severity	Description
Emergency	System is unusable
Alert	Action must be taken immediately
Critical	Critical conditions
Error	Error conditions
Warning	Warning conditions
Notice	Normal but significant condition
Infomational	Informational messages
Debug	Debug-level messages

SNMP MIB Files

This appendix contains the SNMP MIB file for the managed switch.

You can download the MIB file via the product site. Please note the MIB file varies by model.

Structure of the Moxa MIB group package

Moxa support standard MIB and properties MIB. Below are all of folder and related MIB files. Please note that the applicable MIB files may vary across different models.

<Package File Lists>

EX. MOXA_MIB_XXX-XXXX_v1.0_YYYY_MMDD_HHMM.zip //XXX-XXXX means model name

User Role Privileges

This page shows the privilege levels granted to the different authority levels: Admin, Supervisor, and User on Moxa’s Managed Ethernet Series switches. Refer to [System > Account Management > User Accounts](#) for more information on user accounts.

Privileges are indicated as follows:

- **R/W**: Read and write access granted for the relevant settings.
- **R**: Read-only access granted for the relevant settings.
- **-**: No access granted for the relevant settings.

 **Note**

Available settings and options will vary depending on the product model.
